Washington, DC 20426

Re: Northfield Mountain Pumped Storage Project, FERC Project No.2485
Turners Falls Hydroelectric Project, FERC Project No. 1889
Filing of Proposed Study Plan

Dear Secretary Bose:

Pursuant to the regulations of the Federal Energy Regulatory Commission (Commission or FERC), 18 C.F.R. § 5.11, FirstLight Hydro Generating Company (FirstLight), a subsidiary of IPR-GDF SUEZ North America, Inc., Licensee of the Turners Falls Hydroelectric Project (FERC No. 1889) and the Northfield Mountain Pumped Storage Project (FERC No. 2485), encloses for filing the attached Proposed Study Plan (PSP) for the relicensing of the Turners Falls Project and Northfield Mountain Project.

FirstLight received study requests from several federal and state agencies, non-governmental organizations, and individuals (public). In addition, FERC staff issued study requests. FirstLight also included a preliminary list of studies in Section 5 of its Pre-Application Document (PAD). FERC held scoping meetings on the Turners Falls and Northfield Mountain Projects on January 30, 2013 during the day, January 31 in the evening and January 31 during the day to discuss cumulative impacts.

In addition to the study requests, FERC identified deficiencies in the PAD and additional information requests (AIRs). FirstLight has addressed the deficiencies and AIRs in [Section 2.0](#) of the PSP and will also incorporate relevant information into its Preliminary Licensing Proposal or Draft License Application and Final License Application.

FirstLight received over 200 study requests, although many were duplicative and several had common elements. Where possible, FirstLight consolidated common themes and elements into the same study plan resulting in 36 individual PSPs. Per Commission regulation, 18 C.F.R § 5.11(e), FirstLight is required to hold a meeting(s) to discuss the PSP within 30 days of filing the PSP. FirstLight will host meetings on May 14 and 15 to begin discussion of the PSP. FirstLight recognizes; however, that 1-2 days to discuss 36 PSPs is not enough time to review them at the appropriate level of detail. Given this, FirstLight is reserving several additional meetings. The meeting schedule was filed with FERC on April 5, 2013 to provide interested stakeholders advanced notice of meeting dates and logistics. As noted in FirstLight's April 5 filing, on May 14, 2013 from 9:00 am to noon, FirstLight will provide a broad overview of all of

the studies, as required by 18 C.F.R § 5.11(e). The purpose of the “morning” meeting is to present the studies proposed, and the studies not being proposed. The intent is to provide a brief overview of the studies; it is not intended to discuss each study.

The afternoon of May 14 and the meeting schedule thereafter is designed to review and discuss, in greater detail, the individual study plans with the goal of reaching agreement on the methodology and level of effort. The schedule below may be modified, pending progress on reviewing the PSPs. For example, pending progress, some meetings may be cancelled, added to, or held via conference call in lieu of a meeting. If changes to the schedule occur, you will be notified accordingly, as explained below.

We organized “Working Group” meetings along similar resource areas such that not all parties need to attend each meeting.

Resource Area	Meeting Date & Times
Broad Overview of All Studies	May 14, 9:00 am-Noon
Working Group 1: Geology and Soils, Water Resources, Developmental Resources	May 14, 1:00-4:00 pm May 15, 9:00 am-Noon May 15, 1:00-4:00 pm
Working Group 2: Aquatic Resources, Terrestrial, Wetlands, Riparian Resources	May 21, 9:00 am-4:00 pm May 22, 9:00 am-4:00 pm June 4, 9:00 am-4:00 pm June 5, 9:00 am-4:00 pm
Working Group 3: Recreation and Land Use Resources, Aesthetic Resources, Cultural Resources	June 11, 9:00 am-4:00 pm June 12, 9:00 am-4:00 pm June 13, 9:00 am-4:00 pm

As shown in the table above, Working Group 1 will discuss study plans on May 14¹ in the afternoon. FirstLight suggests that during this time, Working Groups 2 and 3 convene to develop agendas for the upcoming meetings.

FirstLight respectfully requests any person interested in attending any of these meetings to conduct the following, which will help facilitate our planning and logistics:

- Go to <http://www.northfieldrelicensing.com> website and click “join our mailing list”, if you have not joined already. FirstLight plans on providing meeting agendas and communicating any potential changes to the schedule above via this website. If you join the mailing list (which requests your email address), you will automatically be notified via email of any changes to the meeting dates, times, location or changes to the schedule.
- **Please RSVP to firstlight@gomezandsullivan.com no later than April 19, 2013 for any of the above meetings you plan to attend.** Please identify which meetings you are interested in attending. This will allow FirstLight to determine if there is sufficient space at the Northfield Mountain Visitors Center to hold the meeting, and if not, to identify a different meeting location. Ideally, we are seeking to hold the meetings at the Visitors Center; however, if the number of people attending exceeds capacity, a different venue will be identified and you will be notified accordingly.

¹ The May 14 afternoon meeting will focus on water resources (water quality and hydraulic model) and developmental resources (operations model); the May 15 meeting will finish discussion of water resources and developmental resources issues from the May 14 meeting as well as discuss geology and soils.

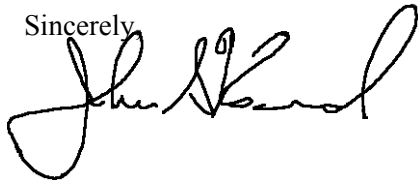

FirstLight looks forward to continuing to work with interested stakeholders in finalizing the study plan for the relicensing of the Turners Falls Project and Northfield Mountain Project. In furtherance of this effort and pursuant to Section 5.12 of the Commission's regulations (18 C.F.R. § 5.12), any comments from interested parties on the PSP must be filed with the Commission by July 14, 2013.

FirstLight is filing the PSP with the Commission electronically. To access the PSP on the Commission's website (<http://www.ferc.gov>), go to the "eLibrary" link, and enter docket number P-1889 (for Turners Falls) or P-2485 (for Northfield) to access the document. FirstLight is also making the PSP available for download on its website. To access the PSP here, navigate to <http://www.northfieldrelicensing.com>, and on click on "documents" tab on the left side of the screen.

In addition to this electronic filing with the Commission, paper copies of the PSP are also available upon request by sending a request via email to firstlight@gomezandsullivan.com. Finally, FirstLight is making available to the public the PSP at the Northfield Mountain Visitor Center at 99 Millers Falls Road, Northfield, MA 01360 during regular business hours.

If you have any questions regarding the above, please do not hesitate to contact me.

Sincerely,

A handwritten signature in black ink, appearing to read "John Howard". The signature is fluid and cursive, with a large initial "J" and "H".

John Howard
Director- FERC Hydro Compliance

PROPOSED STUDY PLAN

TABLE OF CONTENTS

1.0 INTRODUCTION	1-1
2.0 FERC ISSUED PAD DEFICIENCIES AND ADDITIONAL INFORMATION REQUESTS ..2-1	
2.1 FERC PAD Deficiencies.....	2-1
2.1.1 Project Facilities and Operation (FERC Deficiency #1a and #1b)	2-1
2.1.2 Geology and Soils (FERC Deficiency #2a, #2b, and #2c).....	2-1
2.1.3 Water Resources (FERC Deficiency #3)	2-4
2.1.4 Recreation and Land Use (FERC Deficiency #4)	2-4
2.1.5 Aesthetic Resources (FERC Deficiency #5).....	2-4
2.1.6 Cultural Resources (FERC Deficiency #6).....	2-5
2.2 Turners Falls FERC Additional Information Requests	2-15
2.2.1 Proposed Changes to Project Operation (FERC AIR #1)	2-15
2.2.2 Cultural Resources (FERC AIR #2).....	2-15
2.2.3 Socioeconomic (FERC AIR #3)	2-17
2.2.4 Recreation and Land Use (FERC AIR #4).....	2-18
2.3 Northfield Mountain Pumped Storage Project FERC Additional Information Requests	2-35
2.3.1 Proposed Changes to Project Operation (FERC AIR #5)	2-35
2.3.2 Recreation and Land Use (FERC AIR #6).....	2-35
2.3.3 Cultural Resources (FERC AIR #7).....	2-35
3.0 PROPOSED STUDIES	3-1
3.1 Geology and Soils	3-1
3.1.1 2013 Full River Reconnaissance Study	3-1
3.1.2 Northfield Mountain/Turners Falls Operations Impact on Sediment Transport	3-7
3.2 Water Resources	3-17
3.2.1 Water Quality Monitoring Study	3-17
3.2.2 Hydraulic Study of Turners Falls Impoundment, Bypass Reach and below Cabot Station.....	3-28
3.3 Fish and Aquatic Resources	3-36
3.3.1 Conduct Instream Flow Habitat Assessments in the Bypass Reach and below Cabot Station.....	3-36
3.3.2 Evaluate Upstream and Downstream Passage of Adult American Shad	3-68
3.3.3 Evaluate Downstream Passage of Juvenile American Shad	3-74
3.3.4 Evaluate Upstream Passage of American Eel at the Turners Falls Project.....	3-80
3.3.5 Evaluate Downstream Passage of American Eel	3-86
3.3.6 Impact of Project Operations on Shad Spawning, Spawning Habitat and Egg Deposition in the Area of the Northfield Mountain and Turners Falls Projects	3-92
3.3.7 Fish Entrainment and Turbine Passage Mortality Study.....	3-99
3.3.8 Computational Fluid Dynamics Modeling in the Vicinity of the Fishway Entrances and Powerhouse Forebays	3-104
3.3.9 Two-Dimensional Modeling of the Northfield Mountain Pumped Storage Project Intake/Tailrace Channel and Connecticut River Upstream and Downstream of the Intake/Tailrace	3-109
3.3.10 Assess Operational Impacts on Emergence of State-Listed Odonates in the Connecticut River	3-114

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

3.3.11	Fish Assemblage Assessment	3-121
3.3.12	Evaluate Frequency and Impact of Emergency Water Control Gate Discharge Events and Bypass Flume Events on Shortnose Sturgeon Spawning and Rearing Habitat in the Tailrace and Downstream from Cabot Station	3-131
3.3.13	Impacts of the Turners Falls Project and Northfield Mountain Project on Littoral Zone Fish Habitat and Spawning Habitat	3-136
3.3.14	Aquatic Habitat Mapping of Turners Falls Impoundment.....	3-140
3.3.15	Assessment of Adult Sea Lamprey Spawning within the Turners Falls Project and Northfield Mountain Project Area.....	3-143
3.3.16	Habitat Assessment, Surveys, and Modeling of Suitable Habitat for State-listed Mussel Species in the CT River below Cabot Station	3-147
3.3.17	Assess the Impacts of Project Operations of the Turners Falls Project and Northfield Mountain Project on Tributary and Backwater Area Access and Habitat.....	3-152
3.3.18	Impacts of the Turners Falls Canal Drawdown on Fish Migration and Aquatic Organisms	3-159
3.3.19	Evaluate the Use of an Ultrasound Array to Facilitate Upstream Movement to Turners Falls Dam by Avoiding Cabot Station Tailrace.....	3-162
3.4	Terrestrial Wildlife and Botanical Resources	3-166
3.4.1	Baseline Study of Terrestrial Wildlife and Botanical Resources at the Turners Falls Impoundment, the Bypass Reach and below Cabot Station within the Project Boundary	3-166
3.4.2	Effects of Northfield Mountain Project-related Land Management Practices and Recreation Use on Terrestrial Habitats	3-171
3.5	Wetlands, Riparian, and Littoral Habitat	3-176
3.5.1	Baseline Inventory of Wetland, Riparian and Littoral Habitat in the Turners Falls Impoundment, and Assessment of Operational Impacts on Special-Status Species	3-176
3.6	Recreation and Land Use	3-185
3.6.1	Recreation Use/User Contact Survey.....	3-185
3.6.2	Recreation Facilities Inventory and Assessment.....	3-189
3.6.3	Whitewater Boating Evaluation	3-193
3.6.4	Assessment of Day Use and Overnight Facilities Associated with Non- motorized Boats	3-197
3.6.5	Land Use Inventory.....	3-201
3.6.6	Assessment of Effects of Project Operation on Recreation and Land Use	3-204
3.6.7	Recreation Study at Northfield Mountain, including Assessment of Sufficiency of Trails for Shared Use.....	3-206
3.7	Cultural Resources	3-209
3.7.1	Phase 1A Archaeological Survey.....	3-209
3.7.2	Reconnaissance-Level Historic Structures Survey	3-212
3.8	Developmental Resources.....	3-215
3.8.1	Evaluate the Impact of Current and Potential Future Modes of Operation on Flow, Water Elevation and Hydropower Generation.....	3-215
4.0	STUDIES NOT INCLUDED IN THE PSP	4-1
4.1	Geology and Soils	4-1

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

4.1.1	Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage Operations	4-1
4.1.2	Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River.	4-4
4.2	Water Resources	4-9
4.2.1	Watershed Wide Stormwater Model.....	4-9
4.2.2	Climate Change and Continued Project Operations.....	4-12
4.3	Fish and Aquatic Resources.....	4-16
4.3.1	Shad Population Model for the Connecticut River	4-16
4.4	Aesthetic Study	4-19
4.4.1	Noise Level Determination for Northfield Mountain Project Operations.....	4-19
4.5	Recreation and Land Use	4-21
4.5.1	Contingent Valuation Study.....	4-21
4.5.2	Mitigation Impacts of the Connecticut River and Loss of Whitewater Recreation at and above Turners Falls Dam	4-24
4.6	Cultural Resources	4-26
4.6.1	Assess Preservation of Cultural, Historical and Educational Resources	4-26
4.7	Other Project Relative Issues	4-28
4.7.1	Feasibility of Converting the Northfield Mountain Pumped Storage Project to a Closed-Loop or Partially Closed Loop System.....	4-28
4.7.2	Creation of a Decommissioning Fund	4-29

1.0 INTRODUCTION

FirstLight Hydro Generating Company (FirstLight) has initiated with the Federal Energy Regulatory Commission (FERC or Commission) the process of relicensing the 67.709-megawatt (MW) Turners Falls Hydroelectric Project (Turners Falls Project) and the 1,119.2 MW Northfield Mountain Pumped Storage Project (Northfield Mountain Project) (see [Figure 1.0-1](#)). FirstLight is applying for license renewal using the FERC's Integrated Licensing Process (ILP). The license for the Turners Falls Project was issued on May 5, 1980 and expires on April 30, 2018. The license for the Northfield Mountain Project was issued on May 14, 1968 and also expires on April 30, 2018.

As part of the ILP, FERC conducted a public scoping process during which various resource issues were identified. On October 31, 2012, FirstLight filed its Pre-Application Document (PAD) and Notice of Intent (NOI) with the FERC. The PAD included FirstLight's preliminary list of proposed studies. On December 21, 2012, FERC issued Scoping Document 1 (SD1) and preliminarily identified resource issues and concerns. On January 30 and 31, 2013, FERC held scoping meetings for the FirstLight Projects. In accordance with the FERC regulations, site visits typically occur at the same time as the scoping meetings. However, in this case, FERC accelerated the timing of the site visits to avoid a winter site visit to afford an opportunity for on-water tours. Thus, FERC held site visits of the Turners Falls Project, Northfield Mountain Project, on-water Turners Falls Impoundment and the upper reservoir on October 4, 5, and 11. Per the FERC regulations, written comments on the PAD and SD1, and formal study requests must be filed with FERC no later than March 1, 2013. Appendix A contains all of the stakeholder letters that were submitted.

[Table 1.0-1](#), appearing at the end of this section, is a brief summary of the stakeholders that submitted comments, their affiliation, the type of filing², whether the filing addressed the FERC study request criteria, and the submittal date. FirstLight also received various comments/concerns that were not in the form of an official study request. These comments/concerns are summarized, along with a response, in Appendix B.

FirstLight received over 200 study requests, although many were duplicative and several had common elements. Where possible, FirstLight consolidated common themes and elements into the same study plan resulting in 36 individual proposed study plans (PSP). [Table 1.0-2](#) shows by resource category the PSP number, PSP title, the stakeholder name along with their study request number in parenthesis, whether FirstLight proposed to conduct the study or not (yes or no), and when the study is proposed (year). This table can be used to map where a stakeholder request falls into a given PSP or if it was not proposed. FirstLight plans on reviewing this table at the May 14, 2013 morning meeting.

In response to feedback from stakeholders during the scoping process, FirstLight is proposing additional studies and information gathering efforts for the Turners Falls Project and Northfield Mountain Project.

More detailed information on each proposed study is provided in [Section 3](#) of this document. Each PSP includes the following sections per the FERC regulations:

- General description of proposed study;
- Study goals and objectives;

² The FERC filings in Table 1.0-1 fell under one of three topics: 1) testimonials and information presented at the Scoping Meetings, 2) comments, issues and information submitted to FERC, or 3) study requests that met the FERC study criteria in accordance with 18 CFR § 5.9(b)(1)-(7).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Resource management goals of agencies/tribes with jurisdiction over resource;
- Existing information and the need for additional information;
- Nexus between project operations and effects on the resource to be studied;
- Study methodology [including study area];
- Level of effort and cost; and
- Schedule.

Additionally, [Section 4](#) of this document describes study requests that FirstLight did not adopt. FirstLight's rationale for why certain study requests were not adopted is also provided. In many instances, the proposed study did not have a nexus to project operations and effects and would not inform the development of license requirements. In other cases, less costly methodologies were available to gather the requested information.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Table 1.0-2: Study Request and PSP Matrix

Title	Stakeholder Requester(s)	PSP Section	Proposed	Year
Geology and Soils				
2013 Full River Reconnaissance Study	CRSEC	3.1.1	Yes	2013
Study of Turners Falls Erosion	NHFGD (9); Town of Gill (1); LCCLC (1a); FRCOG (1); FCD (1); NMFS (14); CRWC (1)	(Part of 3.1.1)	Yes	2013
Northfield Mountain/Turners Falls Operations Impact on Sediment Transport	NHFGD (6); Town of Gill (2); LCCLC (2a); FRCOG (3); FCD (2); CRWC (2); MADEP (1)	3.1.2	Yes	2014
Shoreline and downstream erosion from water level fluctuation in the impoundment and downstream from peaking operations	NHDES (21c); VANR (1)	(Part of 3.1.1) (Part of 3.1.2) (Part of 4.1.1)	Partial, see section 4.1.1	2014
Water Resources				
Water Quality Monitoring Study	Proposed in PAD; Town of Gill (5); LCCLC (5a); FRCOG (4); CRWC (6); VANR (2); MADEP (2); USFWS (21); NHDES (25c)	3.2.1	Yes	2014
Hydraulic Study of Turners Falls Impoundment, Bypass Reach and below Cabot Station	FERC (1)	3.2.2	Yes	2013-2014
Model River Flows and Water Levels Upstream and Downstream of the Turners Falls Project Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations	NHFGD (16); LCCLC (8a); FRCOG (6); MADFW (13); NMFS (1); CRWC (7); NHDES (14a); USFWS (1); TU (12)	(Part of 3.2.2) (Part of 3.8.1)	Yes	2013-2015
Watershed-wide Stormwater Model	CRJC (Attachment B, pdf page 7)	4.2.1	No	NA
Aquatic Resources				
Conduct Instream Flow Habitat Assessments in the Bypass Reach and below Cabot Station	NHFGD (19); MADFW (2); NMFS (2); CRWC (11); TU (13); USFWS (2); NHFGD (20); MADFW (1); NMFS (3); CRWC (12); TU (14); USFWS (3); TNC (2)	3.3.1	Yes	Accelerated 2013
Evaluate Upstream and Downstream Passage of Adult American Shad	NHFGD (1); Town of Gill (8); NMFS (7); CRWC (14); NHDES (2); VANR (12); TU (2); USFWS (6); MADFW (3); FERC (5)	3.3.2	Yes	2014
Evaluate Downstream Passage of Juvenile American Shad	NHFGD (21); Town of Gill (13); MADFW (6); NMFS (8); CRWC (16); VANR (9); TU (15); USFWS (9)	3.3.3	Yes	2014
Evaluate Upstream Passage of American Eel at the Turners Falls Project	NHFGD (11); MADFW (7); NMFS (9); CRWC (18); VANR (22); TU (8); USFWS (14)	3.3.4	Yes	2014-2015
Evaluate Downstream Passage of American Eel	NHFGD (4); MADFW (8); NMFS (10); CRWC (20); VANR (21); TU (5); USFWS (16)	3.3.5	Yes	2015
Evaluation of Timing of Downstream Migratory Movements of American Eels on the Mainstem Connecticut River	NHFGD (2); MADFW (9); CRWC (19); NHDES (3); VANR (20); TU (4); USFWS (15)	(Part of 3.3.5)	Yes	2014
Impact of Project Operations on Shad Spawning, Spawning Habitat, and Egg Deposition in Area of the Northfield Mountain and Turners Falls Projects	NHFGD (3); Town of Gill (9); MADFW (4); NMFS (5); CRWC (15); NHDES (4); VANR (11); USFWS (5); TU (3); NMFS (5)	3.3.6	Yes	2014, possibly 2015
Fish Entrainment and Turbine Passage Mortality Study	NHFGD (8); Town of Gill (14); MADFW (12); NMFS (13); CRWC (23); TU (7); USFWS (12), FERC (4)	3.3.7	Yes	2015
Computational Fluid Dynamics Modeling in the Vicinity of the Fishway Entrances and Powerhouse Forebays	NHFGD (13); MADFW (10); NMFS (12); CRWC (10); TU (10); USFWS (8)	3.3.8	Yes	2014
Two-Dimensional Modeling of the Northfield Mountain Pumped Storage Project Intake/Tailrace Channel and Connecticut River Upstream and Downstream of the Intake/Tailrace	NHFGD (7); Town of Gill (7); LCCLC (7a); MADFW (11); CRWC (4); TU (6); USFWS (13)	3.3.9	Yes	2014
Assess Operational Impacts on Emergence of State-Listed Odonates in the Connecticut River	MADFW (22)	3.3.10	Yes	2014
Fish Assemblage Assessment	NHFGD (15); Town of Gill (11); CRWC (8); FERC (3); TNC (4); VANR (13); TU (11); USFWS (17); MADFW (21)	3.3.11	Yes	2014
Evaluate Frequency and Impact of Emergency Water Control Gate Discharge Events and Bypass Flume Spill Events on Shortnose Sturgeon Spawning and Rearing Habitat	NHFGD (14); NMFS (4); CRWC (25); USFWS (4)	3.3.12	Yes	2014, possibly 2015
Impacts of the Turners Falls Project and Northfield Mountain Project on Littoral Zone Fish Spawning and Spawning Habitat	MADFW (15); USFWS (18); NHFGD (18); Town of Gill (12); CRWC (9); VANR (18)	3.3.13	Yes	2014
Aquatic Habitat Mapping of Turners Falls Impoundment	FERC (2)	3.3.14	Yes	2014
Assessment of Adult Sea Lamprey Spawning within the Turners Falls Impoundment and Northfield Mountain Project Area	NMFS (11)	3.3.15	Yes	2014
Habitat Assessment, Surveys, and Modeling of Suitable Habitat for State-listed Mussel Species in the CT River below Cabot station	MADFW (20)	3.3.16	Yes	Portions in 2013, if possible; 2014
Assess the Impacts of Project Operations of the Turners Falls Project and Northfield Mountain Project on Tributary and Backwater Area Access and Habitats	NHFGD (5); Town of Gill (10); MADFW (14); CRWC (21); VANR (19); USFWS (19)	3.3.17	Yes	2014
Impacts of Turners Falls Canal Drawdown on Fish Migration and Aquatic Organisms	NHFGD (12); MADFW (17); NMFS (6); CRWC (24); TU (9); USFWS (11)	3.3.18	Yes	2014-2015
Evaluate the Use of an Ultrasound Array to Facilitate Upstream Shad Movement to Turners Falls Dam by Avoiding Cabot Station Tailrace.	NHFGD (22); CRWC (17); USFWS (7)	3.3.19	Yes	2015
Shad Population Model for the CT River	NHFGD (10); MADFW (5); CRWC (13); NHDES (6); TU (1); USFWS (10)	4.3.1	No	NA

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Title	Stakeholder Requester(s)	PSP Section	Proposed	Year
Terrestrial Resources				
Baseline Study of Terrestrial Wildlife and Botanical Resources at the Turners Falls Impoundment, the Bypass Reach and below Cabot Station	Proposed in PAD	3.4.1	Yes	2014
Wildlife Habitat Assessment of Bypass	Montague Board of Selectmen	(Part of 3.4.1)	Yes	2014
Effects of Northfield Mountain Project-related Land Management Practices and Recreation Use on Terrestrial Habitats	FERC (8)	3.4.2	Yes	2014
Wetlands Riparian and Littoral Habitat				
Baseline Inventory of Wetland, Riparian and Littoral Habitat in the Turners Falls Impoundment, and Assessment of Operational Impacts on Special-Status Species	Incorporates 10 requests below	3.5.1	Yes	2014
Integrate Modeled River Flows and Water Levels with Habitat Assessment for State-Listed Riparian Invertebrate Spp.	MADFW (19)	(Part of 3.5.1)	Yes	2014
Assessing Operational Impacts on State-listed Rare Plants in the CT River	MADFW (23)	(Part of 3.5.1)	Yes	2014
Impacts of Water Level Fluctuations on Riparian and Aquatic Veg. Including Invasive Spp. And their Associated Habitats in the TF Impoundment	NHFGD (17); Town of Gill (6); LCCLC (6a); FRCOG (5); CRWC (22); NHDES (15b); VANR (26); USFWS (20)	(Part of 3.5.1 and 3.3.14)	Yes	2014
Recreation and Land Use				
Recreation Use/User Contact Survey	Proposed in PAD; FERC (6)	3.6.1	Yes	2014
Recreation Facilities Inventory and Assessment	Proposed in PAD; FERC (6)	3.6.2	Yes	Accelerated 2012-13
Whitewater Boating Evaluation	NPS (2); AMC, VRC, FCRPT (2); NEF, AMC, American Whitewater (1); FERC (7)	3.6.3	Yes	2014
Assessment of Day Use and Overnight Facilities Associated with Non-motorized Boats	NPS (1); AMC, VRC, FCRPT (1); NEF, AMC, American Whitewater (2) and (3); Montague Board of Selectmen; AMC; CRWC (26)	3.6.4	Yes	2014
Land Use Inventory	FL proposed in PAD	3.6.5	Yes	2014
Assessment of Effects of Project Operation on Recreation and Land Use	FL proposed in PAD	3.6.6	Yes	2014
Recreation Study at Northfield Mountain, Including Assessment of Sufficiency of Trails for Shared Use	NPS (4); AMC, VRC, FCRPT (4); Citizen(Krug)	3.6.7	Yes	2014
Contingent Valuation Study	NEF, AMC, American Whitewater (4)	4.5.1	No	NA
Mitigation Impacts of the Connecticut River and loss of Whitewater Recreation at and above Turners Falls Dam	NEF, AMC, American Whitewater (5)	4.5.2	No	NA
Aesthetics				
Noise Level Determination for Northfield Mountain Project Operations	Citizen (Ondras)	4.4.1	No	NA
Cultural Resources				
Phase 1A Archeological Survey	Proposed in PAD; Montague Board of Selectmen (2-21-2013); Montague Selectmen (2-25-13); FERC (AIR 2)	3.7.1	Yes	2014
Reconnaissance-Level Historic Structures Survey	Proposed in PAD	3.7.2	Yes	2014
Assess Preservation of Cultural, Historical, and Educational Resources	NPS (3); AMC, VRC, FCRPT (3)	4.6.1	No	NA
Socioeconomics				
Feasibility of Converting the Northfield Mountain Pumped Storage Facility to a Closed-Loop or Partially Closed-Loop System	Town of Gill (3); LCCLC (3a); FRCOG (2); FCD (3); CRWC (3)	4.7.1	No	NA
Creation of a Decommissioning Fund	NPS (5); AMC, VRC, FCRPT (5)	4.7.2	No	NA
Other				
Climate Change and Continued Project Operations	Town of Gill (4); LCCLC (4a); MADFW (18); CRWC (5); NHDES (27); USFWS (22)	4.2.2	No	NA
Development Resources				
Evaluate the Impact of Current and Potential Future Modes of Operation on Flow, Water Elevation and Hydropower Generation	Proposed in PAD; TNC (1)	3.8.1	Yes	2013-2015, updated with data from other studies
Develop and Comprehensive and Predictive Model of Electrical Generation System Consisting of 5 Generation Projects along the CT River; Study the Impact and Feasibility of Various Changes in operations on Environmental Resources	FRCOG (7)	(Part of 3.8.1)	Yes	2013-2015, updated with data from other studies

FIRSTLIGHT POWER RESOURCES
PROPOSED STUDY PLAN

Figure 1.0-1
Turners Falls Project and
Northfield Mountain Project
Boundary Map

2.0 FERC ISSUED PAD DEFICIENCIES AND ADDITIONAL INFORMATION REQUESTS

In addition to making their study requests, FERC issued PAD deficiencies as well as additional information requests (AIRs) to supplement the content of the PAD. These deficiencies and AIRs are addressed below.

2.1 FERC PAD Deficiencies

2.1.1 Project Facilities and Operation (FERC Deficiency #1a and #1b)

FERC Def #1a: Please provide the dependable capacity of the Turners Falls Project and the Northfield Mountain Pumped Storage Project and the basis for the determination of the dependable capacity as required per § 5.6(d)(2)(iii)(E) of the regulations.

FirstLight Response: According to *Civil Engineering Guidelines for Planning and Designing Hydroelectric Developments* published by the American Society of Civil Engineers in 1989, dependable capacity is defined as “the load-carrying ability of a power plant under adverse load and flow conditions.” For a standard hydroelectric facility, these conditions would be present during a period of high electrical demand and low flow.

The contracted capacity for the Turners Falls Project with ISO-New England is 68.2 MW (61.8 MW at Cabot and 6.4 MW at Station No. 1). If there were no storage capacity in the Turners Falls Impoundment, the dependable capacity would be lower and would be based on the lowest flow period, which occurs in September (see Figure page 4-30 of the PAD). The highest electrical demand months were estimated from Northfield generation data (see Page 3-33 of PAD) as a true indicator of demand or “adverse load”. For the period 2000-2009, September was the third highest generation (demand) month, behind July and August. For purposes of this analysis, it was assumed that September reasonably represents a low flow/high demand period. The September median flow at the Turners Falls Dam for the period 1941 to 2010 is approximately 4,008 cfs (see page 4-30 of PAD). Assuming all 4,008 cfs is passed through Cabot Station under a net head of approximately 60 feet; the estimated dependable capacity of the Turners Falls Project (without storage capacity) would be approximately 17.7 MW.

The contracted capacity for the Northfield Mountain Project with ISO-New England is 1,124.0 MW, which assumes a full upper reservoir.

FERC Def #1b: Please provide land use maps which include key features as required per § 5.6(d)(2)(ii) of the regulations.

FirstLight Response: Land cover maps were included in the PAD on a larger scale in Figure 4.1.1-1. Land use data is readily available in Massachusetts through the Mass-GIS; land use data is not available for New Hampshire or Vermont. [Figure 2.1.1 \(a-g\)](#) provides a series of land use maps on a smaller scale than that provided in the PAD.

2.1.2 Geology and Soils (FERC Deficiency #2a, #2b, and #2c)

FERC Def #2a: The PAD describes the soils and occurrences; however, it does not provide descriptions of chemical characteristics, erodibility and potential mass movement as required by § 5.6(d)(3)(ii)(B) of the Commission’s regulations. Therefore, to the extent known, please provide a description of chemical characteristics, erodibility and potential mass movement of soils in each project’s area.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight Response: Section 4.2.3 of the PAD contains a discussion of soil types and mapping from Vernon Dam to the Cabot tailrace including the identification of the ten most common soil series found in the Project boundary (PAD Table 4.2.3-1). Although general characteristics of each soil series were included in the PAD, quantitative data pertaining to the chemical and physical properties and erodibility were not discussed. As such, please find the following enclosed in Appendix C:

- Chemical properties including cation-exchange capacity, effective cation-exchange capacity, and pH;
- Physical properties including percent sand, silt, and clay, saturated hydraulic conductivity, organic matter, and erosion factors (Kw, Kf, and T factors); and
- Potential erosion hazard

Soil erodibility factors contained in Appendix C include both the K and T factors. K factor values typically range from 0.02 (least erodible) to 0.64 (most erodible) and can be divided into two sub-categories, Kw and Kf factors. The Kw factor is calculated by taking into consideration the whole soil, while the Kf factor only considers the fine-earth fraction (<2.0 mm diameter). Soil properties affecting the K factor, and therefore the erodibility, can include texture, organic matter content, structure, infiltration, and permeability. The T factor is the maximum amount of annual sheet and rill erosion that permits the fertility and productive capacity of the soil to be maintained indefinitely. T factor values range from 1 ton per acre per year for the most fragile soils, to 5 tons per acre per year for soils that can sustain more erosion without significant productive rainfall. Soil properties affecting T factor values include texture, permeability, available water capacity, and depth to restrictive layer such as rock, clay, or gravel (NRCS, 2013, <http://websoilsurvey.nrcs.usda.gov/app/HomePage.htm>). Data included in Appendix C is parsed based on soil profile depth.

In addition to the NRCS data referenced above, FirstLight has conducted years of river bank erosion studies along the Turners Falls Impoundment resulting in numerous filings with the FERC. As part of the Erosion Control Plan, FirstLight has conducted Full River Reconnaissance (FRR) surveys every 3-5 years since 1998. During these surveys, information such as bank height, bank slope, bank erosion, bank material, and degree of vegetation is collected. In addition to the FRRs, FirstLight recently filed long term monitoring transects within the Turners Falls Impoundment showing geomorphic changes over the last 10+ years. Thus, very specific information on erodibility is contained in these reports.

FERC Def #2a: Additionally, section 5.6(d)(3)(ii)(C) specifies that the PAD provide information on the erosion within the project area. However, while the PAD provides information on erosion around the Turners Falls reservoir, it did not provide any information on the presence of erosion, mass soil movement, slumping or other forms of instability along the bypass reach or the project's power canal. Therefore, pursuant to section 5.6(d)(3)(ii)(C)(2) of the Commission's regulations please provide a description of all known erosion sites within the Turners Falls project's bypass reach and/or along its power canal, and to the extent known, a determination as to the cause of the erosion. The description of each site should include the length of shoreline affected by erosion, the height of the eroded area, and the soil type.

FirstLight Response: FirstLight performed an aquatic mesohabitat study that encompassed the Turners Falls Bypass Reach during 2012. This work entailed walking the bypass reach from the Turners Falls Dam to the Cabot tailrace. The substrate within the bypass reach is primarily bedrock controlled with few areas containing fine substrate; the river-right embankments are naturally armored, high and steep-sided. The river-left embankments are primarily lined with buildings. No areas along the bypass reach river banks were found to be eroding.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight conducts annual inspections of the power canal in a partially dewatered state every September. During 2007-2009, Kleinschmidt Associates investigated an area within the Turners Falls power canal where a slough had formed along the eastern dike (about 400 feet downstream of where the power canal begins to widen) and actions to fix the issue were taking place. The erosion responsible for creating the slough was attributed to considerable sediment buildup toward the western side of the canal, which caused the water velocity along the east bank to be higher than originally intended. The original depth of the west side of the canal was 14 feet, but the sediment accumulation since the canal was built had created a large area where the depth was shallow enough for geese to stand. Additionally, the scouring in the vicinity of the slough was 17 feet below the water level of the canal during dewatering in 2007; by 2008, the scoured hole was 20 feet deep. Removal of sediment from the west bank to the scoured area, along with the addition of stone to stabilize the sediments, resulted in the hole being filled with 42,700 cubic yards (CY) of fill. It was concluded that the work completed in 2009 was a success, with improved flow distribution and lower velocities along the eastern dike. Also, armoring likely increased the stability of the dike with reduced potential for future sloughing. A 300 foot long section of scour at the downstream end of the filled in area was not considered a priority due to being shallow and was not filled in; it is a potential location for future redistribution of silt. A report was filed by Kleinschmidt Associates ("Canal Maintenance Completion Report", July 2009) under Critical Energy Infrastructure Information (CEII).

FERC Def #2b: As specified in § 5.6(d)(3)(ii)(C), please provide a description of reservoir shorelines within the Northfield Mountain upper reservoir. The description should include a description of soils, geometry, and existing armoring and stabilization measures.

FirstLight Response: The shoreline of the Northfield Mountain Reservoir is approximately 3.5 miles long. The majority of the shoreline is the rockfill embankment, but there are also four natural ridges. The 3.5 mile shoreline is comprised of approximately 2.2 miles of rockfill embankment, 0.8 miles of more natural (primarily undisturbed, or human disturbed) soils and 0.5 miles of excavated bedrock (near the intake). The United States Department of Agriculture's online Web Soil Survey application was queried for soil identification and description, for the approximately 0.8 miles of undisturbed soil. An area at the northern end of the reservoir is identified as Woodstock-Millsite-Rock outcrop complex. This soil, which comprises about 1,000 feet of the shoreline, consists of very rocky and rocky soils and rock outcrop. The Soil Survey Report also identified an area about 1800 feet long on the west shore and an area about 1400 feet long on the northeast shore, along natural ridge areas, which consist of generally very fine sand to fine sandy loam. There is some grass and other low growing vegetation on the north shore and west shore areas identified above. The northeast shore area is generally free of vegetation. The upstream face of the embankment consists of large stone fill, with an overall slope of approximately 1:1.8 (V:H), though the upper portion of the slope is somewhat steeper at about 1:1.5 (V:H). There is little to no vegetation growing along this portion of the shoreline, except at very low elevations in some areas, where sediment has deposited.

The upper reservoir, intake channel and intake structure are in the Dry Hill gneiss, which is quite durable and hard rock material. The rocks comprising the west flank of the Northfield Mountain are part of the hard crystalline metasedimentary complex. Near the crest of the mountain, the Dry Hill granite gneiss crops out with the average layering dips from 10° to 12° to the N68°W. Stratification around the project suggests that the ancient sedimentary sequence was metamorphosed by intrusive sills, perhaps from the east. Past studies have indicated that the Dry Hill is considered as an igneous unit, which intrudes the Poplar Mountain formation. The upper portion of the Dry Hill appears to be much less highly metamorphosed, with massive strata separated by thin interbeds of dark biotite and hornblende. Additional information on the geology of the Northfield Mountain Project is included in Section 4.2.2 of the PAD.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FERC Def #2c: As specified in § 5.6(d)(3)(ii)(B), please provide a description of the sediment management in the Northfield Mountain upper reservoir, including monitoring, removal and disposal.

FirstLight Response: On February 15, 2012 FirstLight submitted for FERC approval a *Sediment Management Plan* for the Northfield Mountain Project. As part of this plan, FirstLight has committed to monitoring suspended sediment concentration in the Northfield Mountain Project intake and discharge under a range of operating and ambient river conditions; monitor suspended sediment concentration in the Turner Falls Impoundment at the Route 10 Bridge under a range of flow and water level elevation conditions; conduct bathymetric mapping of the upper reservoir to estimate annual sediment accumulation rates and locations; and, at the end of the monitoring period (2015) propose measures to address the entrainment of sediment into the Project works during upper reservoir drawdown or dewatering activities. For a detailed description of sediment monitoring activities please refer to the *Sediment Management Plan*³.

2.1.3 *Water Resources (FERC Deficiency #3)*

FERC Def #3: Please provide the Northfield Mountain upper reservoir maximum, minimum and mean depth as well as the shoreline length as required per § 5.6(d)(3)(iii)(H) of the regulations.

FirstLight Response: As described in Section 3.2.2 of the PAD, the upper reservoir has a gross storage capacity of 17,050 acre-feet and a surface area of approximately 286 acres at a water surface elevation of 1000.5 feet. The mean depth is calculated to be 59.6 feet. Based on the most recent bathymetric survey of the upper reservoir conducted in 2012, the maximum depth in the upper reservoir is approximately 120 feet when the reservoir is full.

The shoreline of the upper reservoir is approximately 3.5 miles long.

2.1.4 *Recreation and Land Use (FERC Deficiency #4)*

FERC Def #4: For Turners Falls Fishway Viewing Area and Bennett Meadow Wildlife Management Area (WMA) please address the ownership information as specified in § 5.6 (d)(3)(viii)(A).

FirstLight Response: FirstLight owns in fee the Turners Falls Project fish viewing area and the Bennett Meadows Wildlife Management Area.

2.1.5 *Aesthetic Resources (FERC Deficiency #5)*

FERC Def #5: The PAD did not provide information on the description of aesthetic and visual characteristics of the Turners Falls Project dam and adjacent facilities as required by § 5.6(d)(3)(ix). Please provide this information with accompanying photos (if available).

FirstLight Response: As described in Section 3.2.1 of the PAD, the Turners Falls Dam consists of two individual concrete dams—Gill Dam and Montague Dam—that are connected by a natural rock island known as Great Island. The 630-foot-long, approximately 35-foot-high Montague Dam connects Great Island to the west bank of the Connecticut River and includes four gates and a fixed crest section, which is normally not overflowed. The Gill Dam is approximately 55 feet high and 493 feet long, extending from the Gill shoreline (east bank) to Great Island, and includes three tainter spillway gates.

³ FirstLight filed its *Sediment Management Plan* with FERC on July 15, 2011.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

The power canal gatehouse is located on the Montague side of the Connecticut River, forming the abutment for connecting the Montague Dam spillway. The structure is approximately 214 feet long and has masonry and reinforced concrete foundations with a brick walled superstructure.

The power canal is approximately 2.1 miles long and ranges in width from approximately 920 feet in the Cabot forebay (downstream terminus of canal) to 120 feet in the canal proper.

An aerial image of the dam, gatehouse, and upstream ends of the power canal and bypass reach is shown in [Figure 2.1.5a](#). The Gill-Montague Bridge just below Turners Falls Dam provides limited views of the dam and bypass reach.

Station No. 1 is located approximately 0.8 miles downstream from the dam along the bypass reach, where it is connected to the power canal via an approximately 700-foot-long by 100-foot-wide branch canal. The powerhouse consists of brick masonry on concrete foundations and has eight intake bays—each 15 feet wide for a total intake width of 120 feet—narrowing to four penstock outlets. [Figure 2.1.5b](#) shows a view of Station No. 1 from the bypass reach. The powerhouse can generally only be viewed by the public from the bypass reach (access to the powerhouse is gated).

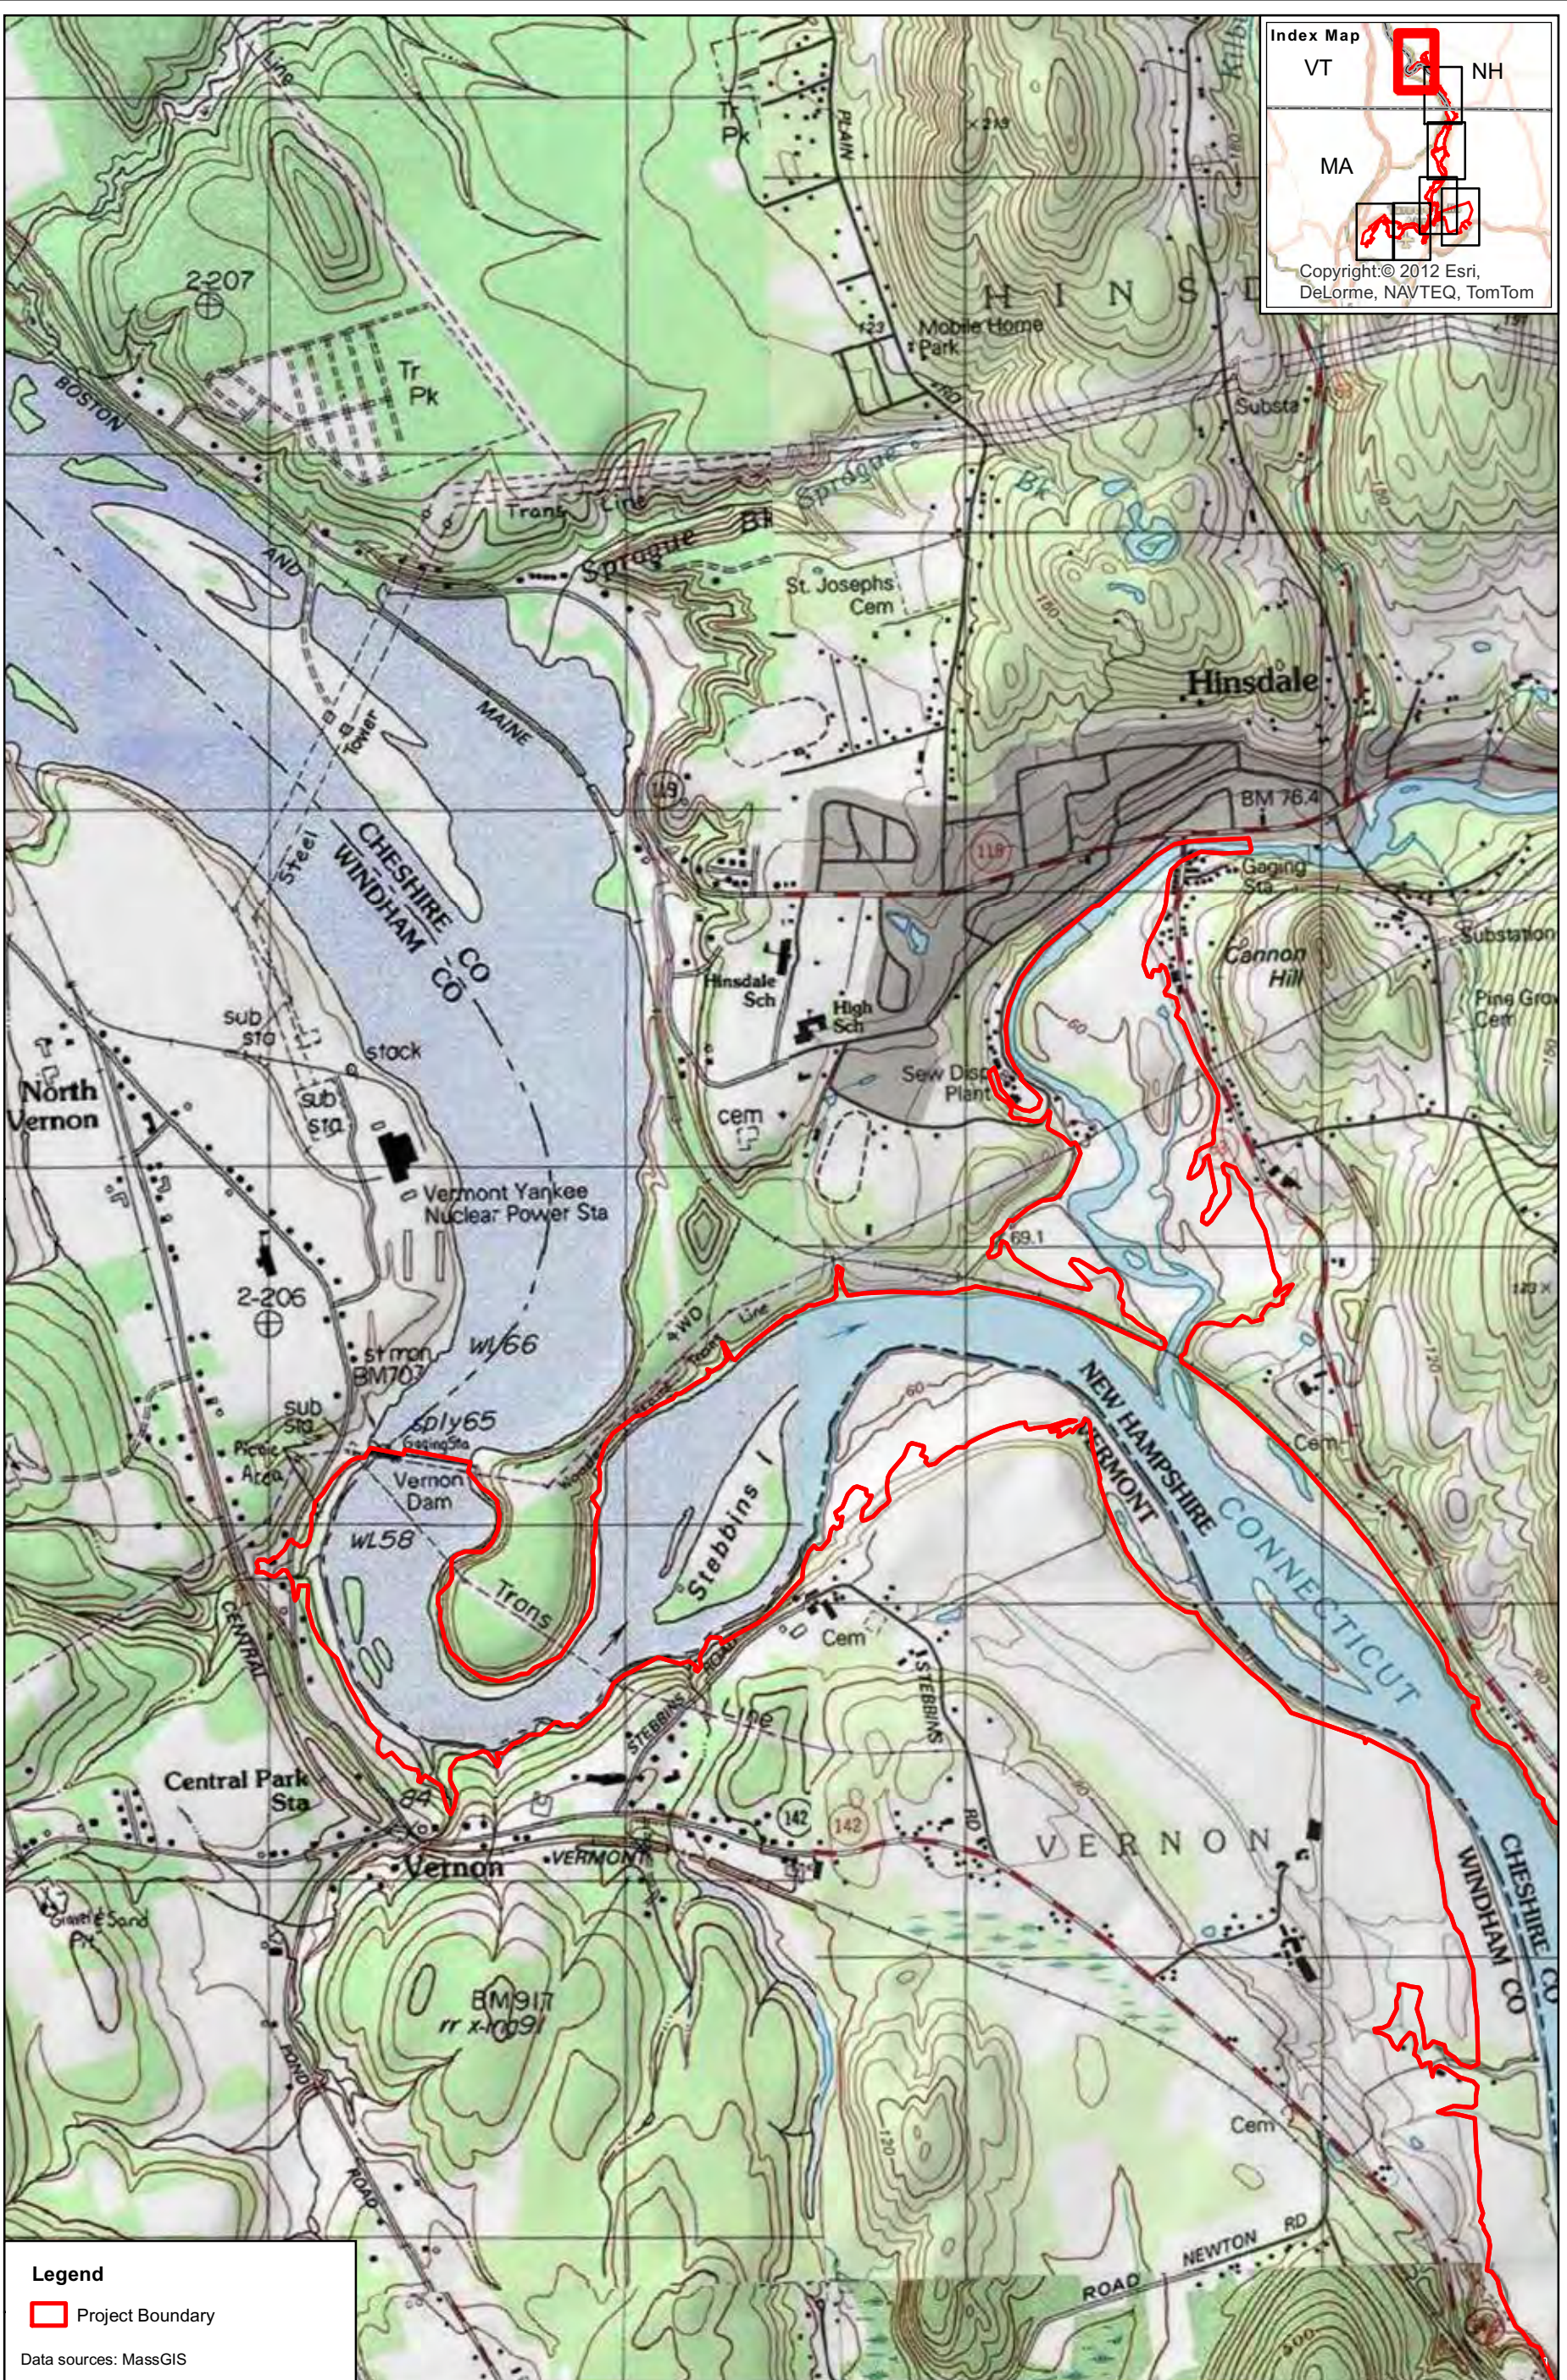

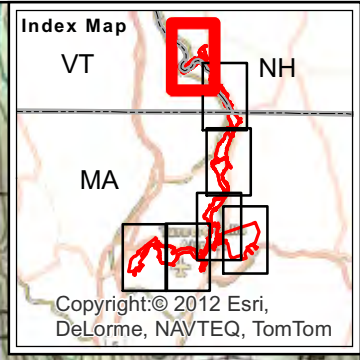

Cabot Station is located at the downstream terminus of the power canal. The powerhouse is a brick and steel structure set on a concrete substructure on a rock foundation, with an intake opening 217 feet wide by 31 feet high. Adjacent to the powerhouse are eight wooden spillway gates. An upstream view of Cabot Station from the Tailwater area is shown in [Figure 2.1.5c](#). As with Station No. 1, the powerhouse can generally only be viewed by the public from the bypass reach (powerhouse access is gated).

2.1.6 Cultural Resources (FERC Deficiency #6)

FERC Def #6: Please provide a description of existing discovery measures for locating, identifying, and assessing the significance of resources as specified in § 5.6(d)(3)(x)(B). Please provide available information on Indian traditional cultural and religious properties as specified in § 5.6(d)(3)(x)(C).

FirstLight Response: FirstLight consults with the applicable State Historic Preservation Office (SHPO), whenever FirstLight proposes to undertake ground-disturbing activity within the Turners Falls Project and Northfield Mountain Project boundaries that require a state or federal permit, in order to locate, identify, and assess the significance of either known or currently unknown cultural resources. In addition, prior to granting permission to others for non-Project uses of Project lands and waters, FirstLight consults with the applicable SHPO in accordance with the procedures of Article 43 of the Turners Falls Project license and Article 52 of the Northfield Mountain Project license. The purpose of such consultation is to determine whether such grants of permission or ground disturbing activity have the potential to adversely affect historic properties.

There are no known Indian traditional cultural properties (TCPs) or religious properties within the Turners Falls Project and Northfield Mountain Project boundaries. One property – The Turners Falls Sacred Ceremonial Hill Site – was determined eligible for inclusion in the National Register of Historic Places as a TCP in 2008. No portion of this ceremonial site is located in either of the Projects' boundaries.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

2.2 Turners Falls FERC Additional Information Requests*2.2.1 Proposed Changes to Project Operation (FERC AIR #1)*

FERC AIR #1: In the PAD you identify alternatives you will consider through the licensing process for potential changes to facilities and operation of the Turners Falls Project including the following: (1) upgrade Station No. 1 with new or rehabilitated turbines, (2) close Station No. 1 and add a turbine generator at Cabot of similar hydraulic capacity to Station No. 1's, and (3) use the full hydraulic capacity of Cabot Station turbines. However, you do not describe the extent or range of the possible modifications to the hydraulic capacity of Cabot Station and Station No. 1. Therefore, so that we may fully understand and evaluate your proposal and determine the appropriate studies needed, please provide detail on the physical and operational changes contemplated at the Turners Falls Project.

FirstLight Response: The combined hydraulic capacity of Cabot Station (13,728 cfs) and Station No. 1 (2,210 cfs) is approximately 15,938 cfs. The maximum hydraulic capacity of the power canal is approximately 18,000 cfs. In addition to Cabot Station and Station No. 1 there are other water entities having water rights to withdraw water from the canal including: Southworth Paper (115 cfs), Turners Falls Hydro, LLC (288 cfs), and a minimal amount of water used by the United States Geological Service (USGS) Conte Anadromous Fish Laboratory. Thus, any increase in hydraulic capacity would be no more than 18,000 cfs less 15,938 cfs, plus water needed for other canal users, or less than approximately 2,000 cfs. Not until studies⁴ are conducted will FirstLight have a better sense of whether to propose additional hydraulic capacity, and if so, whether the additional hydraulic capacity would be located at Cabot or Station No. 1.

2.2.2 Cultural Resources (FERC AIR #2)

FERC AIR #2: In section 5.2.10 of the PAD you propose to conduct a Phase IA Archaeological Survey and Historic Structures Survey of the APE. You also indicate that FirstLight may propose to conduct a Phase IB archaeological and an intensive-level architectural level survey, depending on the results of the Phase IA investigation and after consultation with the Massachusetts, New Hampshire, and Vermont SHPOs. However, you have not provided a map specifically defining the APE, and we are unclear on how you would specifically carry out the various tasks involving your proposed study.

Include in your study proposal that you would also consult with the Vermont, Massachusetts, and New Hampshire SHPOs, and any involved Indian tribe or other interested parties in formulating each of the tasks listed below. As a result, we ask you to include the following in your study proposal for cultural resources:

- a) Define an APE for the project that would include all lands enclosed by the project boundary including both in-water and on-shore project lands and facilities, and lands or properties outside the project boundary where project operations or other project-related activities may directly or indirectly cause changes in the character or use of historic properties, if any historic properties exist. Your study proposal should also include a record of consultation with the Vermont, Massachusetts, and New Hampshire SHPOs, involved Indian tribes, and other interested parties regarding the APE (Once you have defined your APE, send your APE definition and APE map to the Vermont, Massachusetts, and New Hampshire SHPOs and seek their concurrence. The APE

⁴ The study that will best inform potential changes to the hydraulic capacity of the Turners Falls Project is [Study No. 3.3.1 Conduct Instream Flow Habitat Assessment in the Bypass Reach and below Cabot Station](#), as described later in this document.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

definition and map should be included in your study proposal, along with a record of consultation.). Include a detailed map showing all aspects of the APE, including designations of land ownership.

- b) Include the specific techniques on how you would carry out the Phase IA investigation, in addition to any other methods (if needed) by which other cultural resources that may be directly or indirectly affected by the project will be inventoried. Your proposal should include methods for inventorying all archaeological and historic resources that may lie within the APE, including project facilities, non-project architectural resources, and properties of traditional religious or cultural significance. Attention should be given on the assessment of the Turner Falls Ceremonial Site and proposed Great Falls Native Cultural Park, and potential project-related effects to these places (see Town of Montague filing, dated February 6, 2013 and filed on February 20, 2013).
- c) Develop and include in your study proposal a process for evaluating the National Register of Historic Places (National Register) eligibility of all cultural resources during the field inventory stage, and afterwards, through additional second season field investigations (If necessary: If all National Register eligibility determinations cannot be done in either the first or second season of field investigations, a program to follow-up on completing all National Register eligibility determinations of properties located within the APE could be developed and included in the Historic Properties Management Plan (HPMP).), including a strategy for examining, testing, or excavating cultural resources. This process should take into account applicable guidelines and standards promulgated by the Vermont, Massachusetts, and New Hampshire SHPOs.
- d) Elaborate on what methods you would use to identify any existing project-related effects (both direct and indirect) on historic properties recorded during the field inventory, and determine how project operations may affect or potentially affect them.
- e) Include in any study report: (1) a background section on previous work in and around the APE; (2) a culture history of the research area; (3) definition and map of the APE; (4) methods used for the archival research and field pedestrian survey and how the APE was systematically inventoried; (5) the results of the survey and detailed descriptions of the cultural resources found (including a table depicting type of cultural resources, age, property location, and land ownership associated artifacts, existing and potential effects, and National Register eligibility status); (6) results of National Register evaluations for all cultural resources located within the APE (In consultation with the involved parties, once you have determined which cultural resources may, or may not be eligible for the National Register, submit your evaluations to the Vermont, Massachusetts, and New Hampshire SHPOs (as applicable) for concurrence.); and (7) site or resource specific descriptions of existing and potential project-related effects on cultural resources considered to be eligible for inclusion in the National Register. Put a statement in your study proposal you will also prepare a HPMP in consultation with the involved parties and will file a draft HPMP along with your preliminary licensing proposal, and a final HPMP with your final license application (Note that once the Commission finds the HPMP to be final, we would attach it to a programmatic agreement and after noticing the Advisory Council on Historic Preservation, we would execute the programmatic agreement with the Vermont, Massachusetts, and New Hampshire SHPOs, if the Advisory Council on Historic Preservation declines to participate. Execution of the programmatic agreement would evidence that the Commission has resolved any potential adverse effects to historic properties involved with the proposed project.). Among other things, the HPMP should provide site-specific measures to resolve any potential project-related adverse effect to historic properties located within the project's APE. You should use the Guidelines for the Development of Historic Properties Management Plans for FERC

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Hydroelectric Projects, developed by the Advisory Council on Historic Preservation and Commission in May 2002.

- f) Provide a schedule for carrying out all of the various tasks involving your study, including the filing of draft and final reports and HPMPs.
- g) Provide estimated costs associated with the various tasks in your study, along with the costs of report production and crafting the HPMP.

FirstLight Response: Sections [3.7.1](#) and [3.7.2](#) of the PSP contain FirstLight's study plans for the proposed Phase IA Archaeological Survey and Historic Structures Surveys. FERC's AIR requests that the study plans include a definition of the Area of Potential Effect (APE) and a record of consultation with the Vermont, New Hampshire, and Massachusetts SHPOs on the proposed definition of the APE. Typically, however, consultation with and concurrence of the SHPOs regarding an APE, occurs in conjunction with a SHPO's review of the cultural resources study plans so that the SHPOs will have a context in which to determine an APE. The study plans proposed herein include a proposed definition of the APE. The study plans also include a proposal to consult with the Vermont, New Hampshire, and Massachusetts SHPOs to seek their concurrence on an appropriate APE for the Projects. FirstLight will not undertake any cultural resources surveys prior to obtaining SHPO concurrence of the definition of the APE.

FERC's AIR requests that the study plans should give attention to the assessment of the Turner Falls Ceremonial Site, the Town of Montague's proposed Great Falls Native Cultural Park and potential project-related effects to these places. The Turners Falls Ceremonial Site is located well away from the Projects. To the extent that any historic properties within the APE are identified during the course of archaeological studies undertaken in connection with the relicensing that may have a connection to the Great Falls Native Cultural Park, FirstLight will discuss these properties in its archaeological survey reports.

FERC's AIR also requests that the cultural resources study plan provide estimated costs associated with the various tasks in the study plan, along with the costs of report production and crafting the HPMP. The study plans include costs for conducting the Phase IA Archaeological Survey and Historic Structures Survey. These costs include the costs of report production. To the extent that an HPMP is necessary, FirstLight has also provided an estimate for the crafting of an HPMP. This cost will need to be refined after cultural resources surveys are complete and results are available to inform the need for and, if needed, the development of an HPMP.

2.2.3 Socioeconomic (FERC AIR #3)

FERC AIR #3: In PAD section 4.11.1., you cite a document referred to as "PVPC". However, you do not provide the complete citation. Therefore, so that we may fully understand the supporting documentation for the PAD, please provide the complete citation for the PVPC reference in PAD section 4.11.1. If this document is not readily available to the public please provide a copy of the document.

FirstLight Response: The information was obtained from the Pioneer Valley Planning Commission, and is currently available to the general public. The citation is:

Pioneer Valley Planning Commission (PVPC). (n.d). Profile of the Region – The Pioneer Valley.
Retrieved from <http://www.pvpc.org/about/profileofregion.shtml> on 3/13/2013.

2.2.4 Recreation and Land Use (FERC AIR #4)

FERC AIR #4: In the PAD, the current project boundary maps are presented. However, it is difficult to discern ownership and extent of shoreline buffer from the maps and associated narrative in the PAD. Therefore, so that we may fully understand and evaluate your proposal and determine the appropriate studies needed, please describe the project boundary (i.e., is it a metes and bounds survey, and elevation contour, or some combination), and shoreline buffer (e.g., typical distance from normal reservoir elevation to the project boundary, vegetative cover types).

In the PAD, there is no information on the recreation facilities and public access and use on the unnamed island located to the west of the power canal and east of the bypassed reach of the Connecticut River. The PAD also lacks information regarding how access to the island may be restricted by project uses. During the scoping meetings, we learned that the island is accessible by two walkway bridges which are currently closed. Therefore, please provide information on the ownership and management of the walkway, bridges, and an explanation of why the bridges are closed.

FirstLight Response: Detailed aerial maps of the Turners Falls and Northfield Projects showing the Projects' boundaries by metes and bounds survey and/or contour elevations, shoreline buffers, and location of recreational facilities associated with the Projects are contained in [Figures 2.2.4-1 to 2.2.4-15](#).

The first walkway bridge is the Strathmore Footbridge. In an 1873 indenture between Turners Falls Company (TFC), predecessor to the Licensee, and Keith Paper Company (KPC), predecessor to the Town of Montague in which TFC conveyed land to KPC, TFC agreed to "*forever maintain a suitable bridge over said canal.*" After the canal was lengthened and widened in the early 1900's, TFC and KPC reached a new agreement, which was recorded in a 1912 indenture. In this indenture was a lease that allowed TFC and its successors, for a period of 99 years, to maintain and operate a drain or tunnel (Keith drainage pipe) across KPC's land from the canal to the westerly edge of the Connecticut River. In consideration of this, TFC agreed to construct and maintain a steel footbridge from Canal Street to the mill for the purpose of traveling to the mill and carrying "*property, goods and merchandise.*" The mill side of the bridge ends in the mill's second floor. The obligation to maintain the footbridge lasted the duration of the lease. Paper production at the mill stopped in 1994 when the then current mill owner (International Paper) shut down operations. The lease expired March 31, 2011 and the Strathmore footbridge was closed. FirstLight retains title to the footbridge. The Strathmore Bridge has never been used or needed for project purposes.

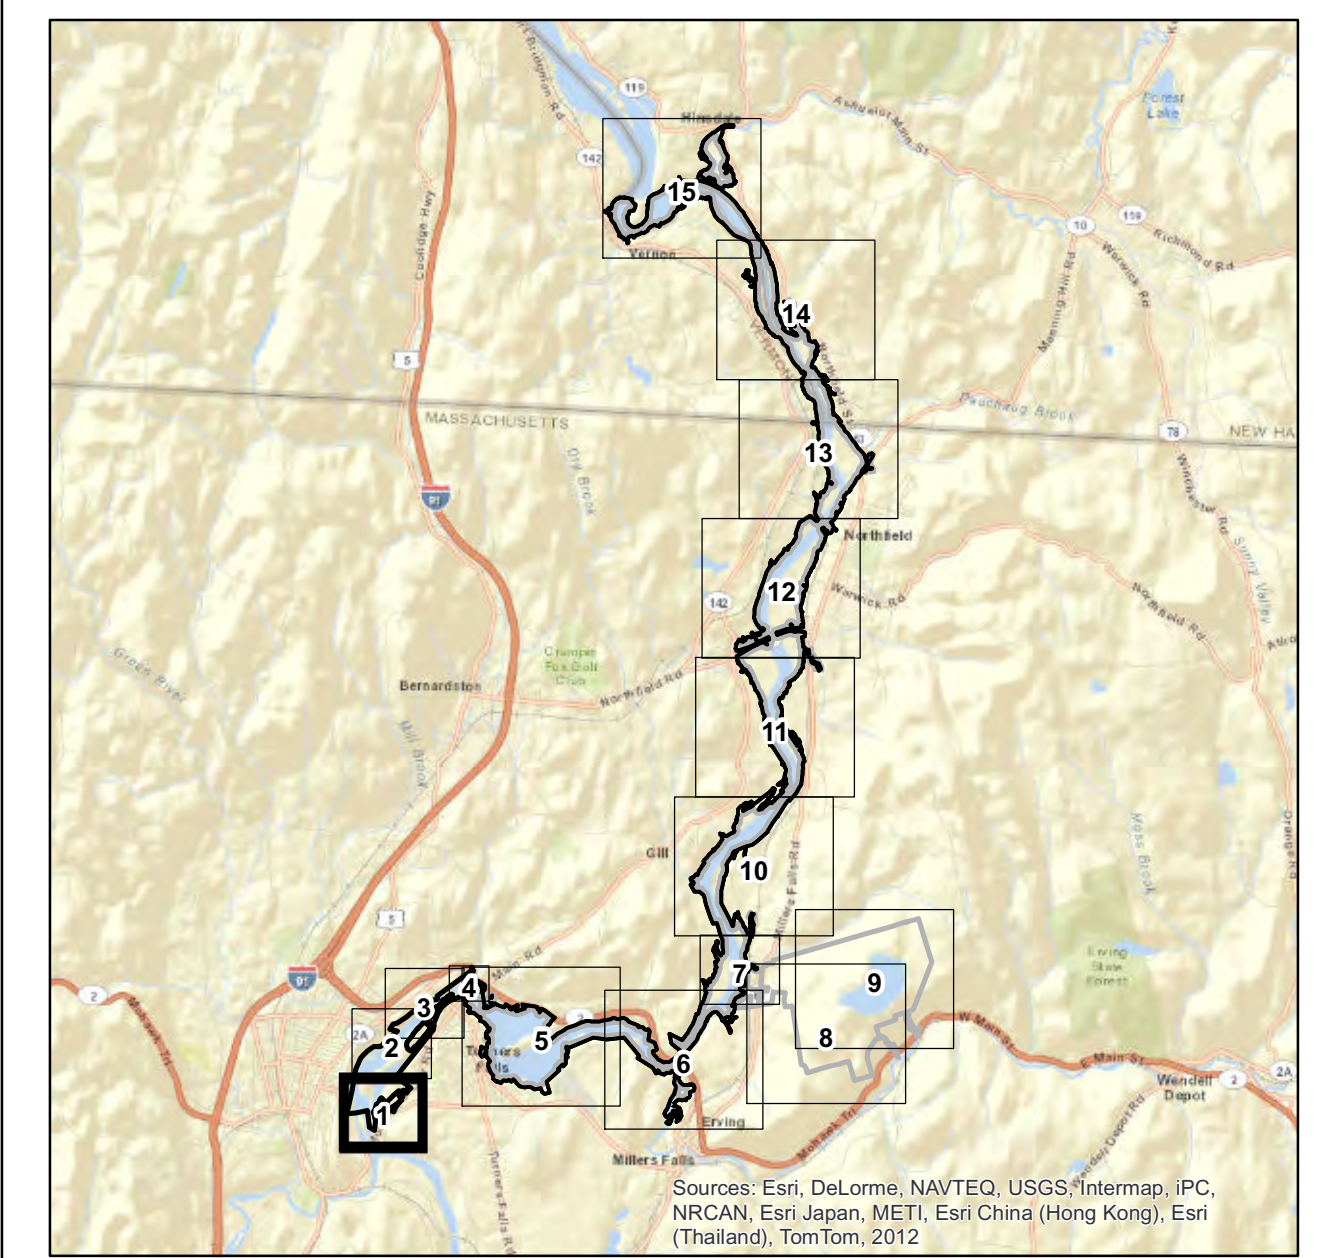

The second bridge is known as the IP Bridge. The IP Bridge resides just downstream of FirstLight's canal headgate house for the power canal. This bridge was present before the canal enlargement and was also modified. Another International Paper Company mill was located on the island near the headgate house, and this bridge was used for mill access. Unlike the Strathmore footbridge, the IP Bridge was built for vehicular use. The bridge is currently posted for a weight limit of 20 ton (2 axle truck) and 30 ton (3 axle truck) with a posted speed limit of 10 miles per hour. The bridge is gated to restrict vehicular access although it is available for emergency use up to the ratings posted. In addition, FirstLight allows pedestrian access across the bridge for recreation purposes, such as fishing access. FirstLight retains title to the IP Bridge.

The State of Massachusetts owns and maintains three other bridges that provide access to the island. The Fifth Street Bridge provides for vehicular access to the industrial end of the island from the Town of Montague for mill access and deliveries. The Sixth Street bridge, located just downstream of the Fifth Street bridge and the Eleventh Street bridge located just downstream of the Sixth Street bridge, are used to access a residential area on the island, the USGS Conte Research Laboratory, the Turners Falls Project No. 1 Station, Branch Canal, Cabot Woods recreation areas, and the back gate of Cabot Station.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

2.3 Northfield Mountain Pumped Storage Project FERC Additional Information Requests*2.3.1 Proposed Changes to Project Operation (FERC AIR #5)*

FERC AIR #5: In the PAD you propose potential changes to facilities and operation of the project including the following: (1) utilize more storage in the Northfield Mountain Project's upper reservoir and, (2) increase the unit and station capacity. However, you do not describe the extent of possible modifications to the hydraulic capacity and to the storage operations within the upper reservoir. Therefore, so that we may fully understand and evaluate your proposal and determine the appropriate studies needed, please provide detail on the physical and operational changes contemplated at the Northfield Mountain Pumped Storage Project.

FirstLight Response: Relative to the Northfield Mountain Project, the maximum additional increase in hydraulic capacity when operating in a generation mode would be approximately 2,000 cfs, or 500 cfs/turbine for potential total station hydraulic capacity of approximately 22,000 cfs (compared to 20,000 cfs currently). Based on preliminary analysis, under a maximum hydraulic capacity of approximately 22,000 cfs, the station capacity would increase from the 1,168 MW to approximately 1,174 MW.

Relative to storage operations, the upper reservoir is licensed to fluctuate between 1000.5 feet msl and 938 feet msl, a total fluctuation of 62.5 feet. As noted in the PAD, the upper reservoir was originally designed to safely retain water up to elevation 1004.5 feet, msl and can be drawn down to elevation 920 feet, msl. The increase in fluctuation provides for an additional 3,009 acre-feet of storage and 1,990 MWHs of energy. FirstLight will be conducting further analysis to determine the feasibility of utilizing more upper reservoir storage capacity.

2.3.2 Recreation and Land Use (FERC AIR #6)

FERC AIR #6: In the PAD, the project boundary maps are presented. However, it is difficult to discern ownership and extent of shoreline buffer from the maps and associated narrative in the PAD. Therefore, so that we may fully understand and evaluate your proposal and determine the appropriate studies needed, please describe the project boundary (i.e., is it a metes and bounds survey, and elevation contour, or some combination), and shoreline buffer (e.g., typical distance from normal reservoir elevation to the project boundary, vegetative cover types).

FirstLight Response: Detailed aerial maps of the Turners Falls and Northfield Projects showing the Projects' boundaries by metes and bounds survey and/or contour elevations, shoreline buffers, and location of recreational facilities associated with the Projects are contained in [Figures 2.2.4-1 to 2.2.4-15](#).

2.3.3 Cultural Resources (FERC AIR #7)

FERC AIR #7: In section 4.10.4 of the PAD, you state that, by letter dated September 30, 2011, the Massachusetts SHPO has recommended that a qualified cultural resources consultant research and compile the information necessary to identify historic and archaeological resources and archaeologically sensitive areas within the project's APE. In section 5.2.10 of the PAD you propose to conduct a Phase IA Archaeological Survey and Historic Structures Survey of the APE. You also indicate that FirstLight may propose to conduct a Phase IB archaeological and an intensive-level architectural level survey, depending on the results of the Phase IA investigation and after consultation with the Massachusetts, New Hampshire, and Vermont SHPOs. However, you have not provided a map specifically defining the APE, and we are unclear on how you would specifically carry out the various tasks involving your proposed study. As a result, in your study proposal for cultural resources we ask you to include the same

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

information, specific to the Northfield Mountain Project, as outlined above for the Turners Falls Project. Include in your study proposal that you would also consult with the Vermont, Massachusetts, and New Hampshire SHPOs, and any involved Indian tribe or other interested parties in formulating each of the tasks.

FirstLight Response: Sections [3.7.1](#) and [3.7.2](#) of the Proposed Study Plan contain FirstLight's study plans for the proposed Phase IA Archaeological Survey and Historic Structures Surveys. FERC's AIR requests that the study plans include a definition of the APE and a record of consultation with the Vermont, New Hampshire, and Massachusetts SHPOs on the proposed definition of the APE. Typically, however, consultation with and concurrence of the SHPOs regarding an APE, occurs in conjunction with a SHPO's review of the proposed study plans so that the SHPOs will have a context in which to determine an APE. The study plans proposed herein include a proposed definition of the APE. The study plans also include a proposal to consult with the Vermont, New Hampshire, and Massachusetts SHPOs to seek their concurrence on an appropriate APE for the Projects. FirstLight will not undertake any cultural resources surveys prior to obtaining SHPO concurrence of the definition of the APE.

FERC's AIR requests that the study plans should give attention to the assessment of the Turner Falls Ceremonial Site and the Town of Montague's proposed Great Falls Native Cultural Park and potential project-related effects to these places. The Turners Falls Ceremonial Site is located well away from the Projects. To the extent that any historic properties within the APE are identified during the course of archaeological studies undertaken in connection with the relicensing that may have a connection to the Great Falls Native Cultural Park, FirstLight will discuss these properties in its archaeological survey reports.

FERC's AIR also requests study plans provide estimated costs associated with the various tasks in the study plan, along with the costs of report production and crafting the HPMP. The study plans include costs for conducting the Phase IA Archaeological Survey and Historic Structures Survey. These costs include the costs of report production. To the extent that an HPMP is necessary, FirstLight has also provided an estimate for the crafting of an HPMP. This cost will need to be refined after cultural resources surveys are complete and results are available to inform the need for and, if needed, the development of an HPMP.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.0 PROPOSED STUDIES**3.1 Geology and Soils***3.1.1 2013 Full River Reconnaissance Study***General Description of Proposed Study**

FirstLight is required by FERC to conduct a Full River Reconnaissance (FRR) Study every 3-5 years in accordance with the Northfield Mountain Project's Erosion Control Plan (ECP) and to satisfy compliance requirements associated with the Turners Falls Project and Northfield Mountain Project licenses. The next FRR is slated for November 2013 during leaf off. With the impending relicensing effort and timing of the next FRR, FERC contacted FirstLight and indicated that the 2013 FRR should be folded into the relicensing.

Prior to FERC contacting FirstLight, FirstLight had been working with the Franklin Regional Council of Government (FRCOG), Connecticut River Watershed Council (CRWC), and Landowners and Concerned Citizens for License Compliance (LCCLC) on crafting a Quality Assurance Project Plan (QAPP). The goal of the QAPP is to ensure consistency with data collection methods such that any future FRRs would allow for direct comparison. A draft version of the QAPP and FRR was circulated to the FRCOG, CRWC and LCCLC for review and comment, and a meeting was held. Since the QAPP/FRR is now incorporated into the FERC relicensing process, FirstLight developed this study plan based on the study plan criteria. However, as part of this study, stakeholders should also review Appendix D, which includes the QAPP/FRR. The QAPP/FRR contains significantly more detail than this study plan.

Several stakeholder groups submitted study requests pertaining to: 1) Study of shoreline erosion caused by Northfield Mountain Pumped Storage operations and 2) Impact of Turners Falls and Northfield Mountain Project operations on sedimentation and sediment transport. Study requests related to these subjects were received from: Massachusetts Department of Environmental Protection (MADEP), New Hampshire Fish and Game Department (NHFGD), New Hampshire Department of Environmental Service (NHDES), FRCOG, Franklin Conservation District (FCD), CRWC, LCCLC and the Town of Gill. Portions of these study requests were incorporated into this study, while other portions are discussed in [Study No. 3.1.2 Northfield Mountain/Turners Falls Operations Impact on Sediment Transport](#).

The proposed FRR study calls for conducting a boat survey along the riverbanks of the Turners Falls Impoundment to document erosion using consistent methods and procedures to allow for comparisons of any future FRRs. It is not designed to determine the cause of erosion; that issue is addressed in [Study No. 3.1.2 Northfield Mountain/Turners Falls Operations Impact on Sediment Transport](#)

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The purpose of the FRR study is to conduct a reconnaissance level evaluation of erosion in the Turners Falls Impoundment without reference to the cause of the erosion. The goals and objectives of this study are to:

- Develop a QAPP for the FRR;
- Document existing riverbank features and characteristics;
- Accurately map and scientifically describe all portions of the Turners Falls Impoundment where active or recent bank erosion is occurring;

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Spatially define, using a global positioning system (GPS), the transition points or end points where riverbank characteristics or features change from one classification to another;
- Map land use practices adjacent to the river (note that land use maps along the riverbanks are being developed as part of the FERC relicensing process). Describe areas that are directly observed and linked to bank erosion.
- Develop classification techniques of observations into a definable and repeatable methodology;
- Develop distribution and summary statistics of conditions in 2013, assess change in riverbank conditions in context of the ECP since implementation, analyze change in condition of the riverbank since the 2008 FRR; and
- Develop a final report, including maps delineating features identified in the field that will document and summarize the findings of the 2013 FRR.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

As part of the current license requirements of the Northfield Mountain and Turners Falls Projects FirstLight is required to conduct a FRR every 3-5 years. Given the impending relicensing effort and timing of the next FRR (November 2013), FERC contacted FirstLight and indicated that the 2013 FRR should be folded into the relicensing.

In addition, MADEP, NHEFD, NHDES, NMFS, NHDES, and VANR, as well as stakeholder groups FRCOG, FCD, CRWC, LCCLC, and the Town of Gill, all submitted study requests pertaining to soils and geology. Study request tasks that were related directly to the goals and objectives outlined in the Study Goals and Objectives section above were incorporated in this reconnaissance level study. All other tasks were included in [Study No. 3.1.2 Northfield Mountain/Turners Falls Operations Impact on Sediment Transport](#) or not included in the PSP.

Resource management goals of the Agencies related specifically to this effort include documenting and describing the changes to banks upstream and downstream of riverbank restoration projects, including bank recession.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

In 1998, Simons & Associates (S&A) developed the “*Erosion Control Plan for the Turners Falls Pool of the Connecticut River (ECP)*” (1999). As part of the ECP, FRR studies were conducted in 1998, 2001, 2004, and 2008 to document existing riverbank features and characteristics. The ECP and FRR studies are readily available for use as support documentation or as tools to compare past and present riverbank conditions.

Extensive research has been conducted evaluating erosion along the Connecticut River in the Turners Falls Impoundment; such research includes:

Connecticut River Joint Commissions and Trails Conservation Assistance Program of the National Park Service through the Connecticut Valley Partnership. (1996). *River Dynamics and Erosion*. Charlestown, NH: Author.

Field Geology Services. (2004). *Fluvial Geomorphology Assessment of the Northern Connecticut River, Vermont and New Hampshire*. Farmington, ME: Author.

Project Nexus (18 CFR § 5.11(d)(4))

The Connecticut River is an alluvial river, subject to natural processes that result in dynamics such as lateral shifting, erosion, and deposition. These natural processes and dynamic response of the river is further affected by land-use practices, modified flow/water level regime, motorized boating, and other factors. Due to a variety of factors, the riverbanks along the Connecticut River, not just in the Turners Falls Impoundment, have a history of being susceptible to erosion. In accordance with the existing license requirements of the Turners Falls and Northfield Mountain Projects, a reconnaissance survey of the Turners Falls Impoundment was conducted in 1998 to map riverbank characteristics and prioritize erosion sites to be considered for stabilization. As a result of this work, the “*Erosion Control Plan for the Turners Falls Pool of the Connecticut River (ECP)*” was developed by Simons and Associates (1999). The ECP requires FirstLight to conduct FRR studies every 3-5 years to continually monitor and evaluate erosion conditions throughout the Impoundment. As part of the FERC relicensing of the Turners Falls and Northfield Mountain Projects, the Commission has requested that the 2013 FRR be folded into a relicensing study.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The following methods, as outlined in the QAPP (Appendix D), will be used to document existing riverbank features and characteristics and to analyze any change in riverbank conditions since the 2008 FRR. Note that the task descriptions provided below summarize the more detailed tasks outlined in the QAPP (Appendix D). It is recommended that stakeholders fully review Appendix D.

This study will include the entire length of the Turners Falls Impoundment from Vernon Dam to Turners Falls Dam to show the full range of conditions that are observed within this reach and to be consistent with previous FRRs.

The following methods will be used to document riverbank features and characteristics and to analyze change in riverbank conditions since the 2008 FRR. Study methods will consist of the following tasks: 1) document existing riverbank features and characteristics; 2) spatially define riverbank feature transition points; 3) map and develop distribution of riverbank features and characteristics including summary statistics, evaluation of conditions in 2013 in context with historical changes since implementation of the ECP, and analyze changes in conditions from previous FRR studies; and 4) develop a final report and mapping.

Task 1: Document Existing Riverbank Features and Characteristics

Current riverbank features and characteristics will be identified and defined through the use of a pre-determined matrix of nine riverbank criteria. This matrix (see [Table 3.1-1](#)) includes characteristics such as slope, vegetation, height, and riverbank sediment to name a few (consistent with previous FRRs as well as other riverbank assessment approaches). Using the 2008 FRR matrix as a guide, FirstLight will identify areas of improvement within the existing matrix; however, for the sake of consistency with the previous FRRs all features and characteristics in the 2008 matrix will be retained and utilized in future FRRs, while perhaps considering additional features and characteristics as is being done with the land-based component of the reconnaissance. The classification of features and characteristics found within the matrix will be based on field observations and not quantitative measurements (consistent with other FRRs). FirstLight will use the comprehensive matrix and document by example photographs representing all the features and characteristics as shown in the QAPP for use in 2013 as well as for any future FRR studies. In doing so, FirstLight will ensure that all future FRR studies are conducted in a consistent manner to make the task of comparing past and present conditions more consistent and direct. [Table 3.1-1](#) provides the 2008 matrix of riverbank features and characteristics proposed for the boat-based component of the FRR.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Table 3.1-1: Connecticut River– Turners Falls Impoundment Riverbank Characteristics Matrix, Boat-based field data logging worksheet

Upper Riverbank Slope	Overhanging	Vertical	Steep (>2:1)	Moderate (4-2:1)	Flat (<4:1)	
Lower Riverbank Slope	Vertical	Steep (>2:1)	Moderate (4-2:1)	Flat (<4:1)		
Upper Riverbank Sediment	Silt/Sand	Gravel	Cobbles	Boulders	Rock	Clay
Lower Riverbank Sediment	Silt/Sand	Gravel	Cobbles	Boulders	Rock	Clay
Upper Riverbank Height	Low (<8 ft.)	Medium (8-12 ft.)	High (>12 ft.)			
Degree Upper Riverbank Vegetation	Heavily Vegetated	Moderately Vegetated	Sparsely Vegetated	None to Very Sparse		
Mass Wasting	Little/None	Some	Extensive			
Erosion Type	None	Overhanging Bank	Undercut Toe	Notching	Slide	
Lower Riverbank Vegetation	None	Heavy	Moderate	Sparse		

In addition to the classification efforts outlined above geo-referenced video photography will be conducted to capture riverbank conditions and characteristics. Red Hen Systems (also used in 1998, 2001, 2004, and 2008) provides hardware and software that collects geo-referenced video in the field and brings that data into desktops or web-based maps. The geo-referenced videos will serve as a means for data control and reference checking back to the photos guiding the classification process that are included in the QAPP, during post-processing efforts.

While the majority of riverbank evaluation and classification will be boat based, a ground-based component will be implemented during this task. Ground-based field work will consist of walking along the top of the riverbank at specific areas of interest. The selection of these areas will be based on land-use types, boat-based riverbank observations such as tension cracks, evidence of mass-movements/wasting and any other types of erosion. [Table 3.1-2](#), provides an overview of attributes to be captured during ground-based observations. The location of the beginning and end points of these features will be collected via sub-meter GPS. Observations will be entered into the data-logger and backed up by geo-referenced digital photograph and/or video documentation.

Table 3.1-2: Ground-Based Erosion Evaluation Form

Town /East or West Bank	Coordinates Start-End	Distance from River	Height above River	Type of Erosion*	Description/ Comments

* Type of Erosion: Erosion types identified will include, but not be limited to, the following: tension cracks, gullies, slides, slips, slumps, falls

Task 2: Spatially Define Riverbank Feature Transitions

The location of transition points, or end points, from one riverbank feature or classification to another will be captured via GPS in a standard coordinate system (i.e. NAD 83 State Plane or UTM coordinates). In order to capture these locations, FirstLight will utilize a sub-meter GPS unit, a data-logger, and a laser range-finder for all data collection. The individual conducting the classification will select a point of

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

transition from one category of riverbank to another and “shoot” the point with the laser-range finder. Once the point has been “shot” the location of that point is stored on the data logger. The features and characteristics of the next segment of riverbank will be classified and verbally transmitted to the individual operating the data logger. This individual will then enter the classification on the data logger for storage.

Task 3: Develop Maps, Summary Statistics, Evaluation of Conditions, and Analyze Changes in Condition since Implementation of ECP and from 2008 FRR

Segmentation of all riverbank features and characteristics will be developed showing the longitudinal extent and distribution along the Turners Falls Impoundment. Summary statistics quantifying the lengths of features and characteristics will be calculated. Conditions in 2013 will be evaluated based on comparisons over time of the river going back as far as the implementation of the ECP.

Once all field efforts, post-processing, and development of the spatial segmentation of riverbanks based on field classification of features and characteristics is completed, analysis of the 2013 field data will be conducted to develop summary statistics of the riverbank classification. Maps showing all riverbank features and characteristics within each feature will be developed in ArcGIS showing results of the 2013 FRR. Geo-referenced video from the boat-based field work and geo-referenced photographs from the land-based field work will be available in documenting and analyzing the condition of riverbanks. Comparisons of riverbank conditions will be made back to the time of the initial FRR (in 1998 as part of the ECP) and other FRRs using overall summary statistics of riverbank features and characteristics and photography. A comparison of the 2013 FRR will be made to the previous FRR’s using summary statistics and analysis in ArcGIS, accounting for any differences in methods and considering the accuracy of the technology utilized in collecting the spatial component of the data. Comparison efforts may include analyzing changes in the length of riverbank shoreline experiencing erosion, severity of erosion, length of riverbank stabilization, success of erosion remediation efforts, identification of new erosion areas, etc.

The FRR will include mapping and description of riverbank features and characteristics where active or recent bank erosion is occurring at the time of the field work. Areas of erosion adjacent to previous bank stabilization will be identified and discussed in context of the type of stabilization utilized. Additionally, land-use practices that are related to riverbank erosion processes will be mapped as part of the land-based component of the FRR.

Sediment classification of the upper and lower riverbanks is included in the matrix of features and characteristics, with maps showing location and extent of the range of sediment types included in the FRR. Sediment classification is sub-divided into 6 key categories ranging from clay, silt/sand, up through boulders and bedrock; allowing easy understanding of which areas consist of erodible soils and which are not – including the location and extent of bedrock.

Task 4: Develop Final Report and Mapping

Following post processing and analysis of field data, a final report documenting the methodology and results of the 2013 FRR study will be generated, including discussion of summary statistics and comparisons over time with previous FRRs. In addition, maps will be generated in ArcGIS delineating all features and characteristics captured during field efforts and summary maps. Maps will be made available digitally as well as in the final report.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort defined above is adequate to conduct a comprehensive full river reconnaissance study. The estimated cost for this study is between \$200,000- \$250,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight is proposing to conduct the field component of this study in the fall (ideally November 2013) during leaf-off conditions. Based on the ILP schedule, and assuming there is no dispute with this particular study, FERC would issue its study plan determination letter by September 12, 2013. This would allow sufficient time to conduct the November 2013 FRR. However, if an agency with mandatory conditioning authority disputes this particular study, FERC would not issue its study plan determination letter until December 11, 2013. Thus, FirstLight would have to delay conducting the 2013 FRR until November 2014.

*3.1.2 Northfield Mountain/Turners Falls Operations Impact on Sediment Transport***General Description of Proposed Study**

This study was requested by the MADEP; however, several other stakeholders (FRCOG-2⁵, CRWC-2, FCD-2, Town of Gill-2, and LCCLC-2a) had a similar study request containing many of the same study objectives and elements as the MADEP. The latter group requested the same study entitled: “*Study the Impact of Operations of the Northfield Mountain Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River*”. FirstLight is addressing many of their study objectives/elements in this study; however, those study objectives/elements not proposed are summarized in [Section 4.0](#) Studies Not Included in the PSP- see [Study No. 4.1.2](#).

The study calls for evaluating the causes of erosion in the Turners Falls Impoundment, determining if they are related to project operations, and identifying measures to stabilize the sites. In addition, the study calls for evaluating options to minimize sediment transport through the upper reservoir and power canal.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The study goals include:

- Assess management measures available to minimize sediment transport through the Turners Falls Canal and from the Upper Reservoir at Northfield Mountain during and after maintenance drawdowns; and
- Conduct a focused investigation of bank instability in the Turners Falls Impoundment where there is a causative relationship between the presence of fine-grained soils susceptible to instability due to water level fluctuations associated with hydropower operations.

The study results should provide information sufficient to understand current and proposed effects of water level fluctuations, both natural and anthropogenic, and to identify sites where biostabilization techniques or other measures may be beneficial to water quality. The purpose of the study is to focus attention and resources on that fraction remaining as per the PAD of the river banks within the Turners

⁵ The “-2” refers to the stakeholders’ study request number.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Falls Impoundment which are scientifically established to be susceptible to erosion due to repeated soil wetting and drying.

The specific objectives include:

- a. Accurately map and scientifically describe that portion of the Turners Falls Impoundment where active or recent “bank” “erosion” is occurring (maybe as much as 18% of the banks in the Turners Falls Impoundment)—all terms should be precisely defined, and linked to jurisdictional definitions, whenever possible;
- b. Note any of the areas of active or recent bank erosion that have been the locus of prior bank stabilization and identify the method of stabilization implemented at that locus;
- c. Within the mapped areas of active or recent bank erosion, establish and designate fixed, recoverable transects; Transects should be representative of various reaches and utilize, to the extent practicable, existing data.
- d. Analyze soils (classification, structure, parent materials, texture, hydric regime, position on landscape, chemistry, and most importantly engineering dynamics such as susceptibility to slope failure) at each transect;
- e. Along these same transects collect cross-section data related to bathymetric and riverine hydrology, most especially as they relate to jurisdiction and water level fluctuation. Determine the precise elevation of the Ordinary High Water Mark (OHWM), normal impoundment elevation, maximum and minimum daily range elevations. Evaluate the subsurface hydrology at each transect, but above OHWM, to account for groundwater influences on soil slumping.
- f. Once the initial data is collected and organized, a geotechnical engineer will evaluate field data plotted at each cross section on various transects to analyze conditions of slope instability and erosion. This analysis will focus on slope conditions, relative susceptibility of bank failure due to repeated wetting and drying. Soil engineering analysis e.g. slope stress, failure planes, shear stress, “Plasticity Index” and “Erosion Factors”, would help guide direction of the stabilization efforts. Of special concern is to analyze all causes for slope instability, and to separate out those locations where repeated wetting and drying is a primary factor. This analysis should investigate site soils within the range of daily fluctuation of water levels extending up to and including the capillary zone. All water level data and soil hydrology should be plotted on cross sections to allow for proper analysis.
- g. Map land use practices that are directly observationally linked to bank erosion directly beneath and/or proximate to them, and target these areas for employment of best management practices;
- h. Superimpose on the 18% of the impoundment which comprises the “study area” a “sensitive receptors” overlay, which will map in detail the position of bank-nesting bird species, rare species occurrences, “vegetated shallows”, and other sensitive and agreed to factors which might make such sites less preferable as locations for biostabilization, in favor of less sensitive sites;
- i. Transects will then need to be periodically revisited and data collected, for use in determining progression of relative erosion at each, the effectiveness of biostabilization at transects where this technique has been employed, and potential differences in soil profiles at different transects to withstand repeated, daily wetting and drying.
- j. Determine through accurate, repeatable, scientifically based mapping what fraction of the banks of the impoundment are susceptible to or experiencing erosion due to repeated wetting and drying of the soil column; eliminate all other “banks” within the impoundment from further erosion study, including areas in which bedrock predominates; soils/substrates are presently stable; or where hardscape stabilization has already been installed.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The 2012 Integrated List of Waters shows the segment from VT/NH state line to the Turners Falls Dam (MA34-01 and MA34-02) as impaired and considered “*Water Requiring a TMDL*” due to “*Other flow regime alterations*”, “*Alteration in stream side or littoral vegetative covers*” and “*PCB in Fish Tissue*”. In addition, the segment below the Turners Falls Dam to the confluence with the Deerfield River (MA34-03) is also shown as impaired by these causes as well as total suspended solids. MADEP notes that the requested studies will assist it in issuing a Water Quality Certification that complies with the State and Federal Clean Water Acts.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Extensive research has been conducted evaluating the causes and effects of erosion along the Connecticut River in the Turners Falls Impoundment; such research includes:

Connecticut River Joint Commissions and Trails Conservation Assistance Program of the National Park Service through the Connecticut Valley Partnership. (1996) *River Dynamics and Erosion*.

In addition, the following information is available to help inform this study:

- Bathymetric mapping of the Turners Falls Impoundment was completed in 2006 and bathymetric mapping of the upper reservoir was completed in 2010, 2011 and 2012.
- On January 22, 2013, FirstLight filed with FERC plan maps showing the location of 22 transects located in the Turners Falls Impoundment. Also provided were cross-section plots of these transects that have been surveyed twice annually since 1998. It is unclear at this juncture whether any of the 22 transects could be used as part of this study as further assessment is needed to determine if any of the 22 transects are in locations where erosion is caused by water level fluctuations due to hydropower operations.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Section 4.2.3 of the PAD contains a discussion of soil types and mapping from Vernon Dam to the Cabot tailrace including the identification of the ten most common soil series found in the Project boundary (PAD Table 4.2.3-1). Soils maps along the riverbanks were included in the PAD. Included as part of FERC's AIR (see [Section 2.0](#)) for the top ten most common soils, FirstLight has included in Appendix C⁶ the following other data that will help support MADEP study objective (d):
 - Relative to soil chemical properties: depth, cation-exchange capacity, effective cation-exchange capacity, and pH.
 - Relative to soil physical properties: percent sand, silt, and clay, moist bulk density, saturated hydraulic conductivity, available water capacity, linear extensibility, organic matter and erosion factors (Kw, Kf, and T).
- FirstLight maintains paper copies of their log sheets that include hourly data on flows, water elevations and generation. For the period 2000-2009, FirstLight has converted the paper copies to electronic data. The following data is available that will be of assistance in this study.
 - Relative to flows, FirstLight has Vernon discharges, and adds to this USGS flows as recorded at the Ashuelot and Millers River to estimate total inflow. FirstLight also has estimated flows passed through the gatehouse and estimated flows passed over the Turners Falls Dam.
 - Relative to water levels, FirstLight maintains water level recorders on the same vertical datum in the Turners Falls Impoundment at the following locations a) immediately below Vernon Dam, b) directly below the Northfield Mountain tailrace, c) at the boat barrier buoy line approximately 1,500 feet upstream of the Turners Falls Dam and d) at the Turners Falls Dam (see Figure 4.3.1.3-1 in PAD for locations).
- FirstLight also maintained water level recorders on the same vertical datum for approximately the period May 1 through mid-August at two additional locations in the Turners Falls Impoundment - at West Northfield Road (near the VT/NH/MA border) and at the Route 10 Bridge (see Figure 4.3.1.6-1 in PAD for locations).
- Two hydraulic models of the Turners Falls Impoundment are available using the 2006 bathymetry including a steady-state one-dimensional HEC-RAS model and a two-dimensional RIVER2D model. FirstLight recently used the HEC-RAS model to evaluate at what flow hydraulic control of the river shifts from the Turners Falls Dam to the French King Gorge. The analysis also demonstrated that the upstream influence of the Turners Falls Project extends to approximately 9,000 feet below the Vernon Dam. This analysis was filed with FERC on February 22, 2013.
- Past reports contain significant background information on the geomorphic history of the Connecticut River, which provides some context.
- Pressure transducers were used to measure water level fluctuations in the river and groundwater near Bennett Meadow on the west bank just below the Route 10 Bridge. One transducer was placed in the river, and three (52 ft, 65 ft and 210 ft from the river) were placed in monitoring wells along a line perpendicular to the riverbank. The field work was conducted from mid-July

⁶ The soil information was obtained from the United States Natural Resources Conservation Service.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

1997 through February 1998. These data provide information on the groundwater elevation and hydraulic gradient.

- Hydraulic (near shore velocity), bank material sampling, and suspended sediment sampling was conducted over a range of flow conditions from 1997 through 2011. These data provide information on velocity, hydraulic shear stresses, particle size distributions, and sediment transport.
- Data on boat waves was collected on July 12-13, 1997 and July 26-27, 2008. At several locations, temporary staff gages were installed to document wave amplitude and frequency using videotape. Suspended sediment samples were also collected in the area where the waves impacted the shoreline.
- Two reports addressing riverbank erosion were filed with FERC on January 8, 2013 as follows:
 - Simons & Associates. (2012). *Riverbank Erosion Comparison along the Connecticut River*. Prepared for FirstLight. Midway, UT: Author.
 - Simons & Associates. (2013). *Analysis of Erosion in Vicinity of Route 10 Bridge Spanning the Connecticut River*. Prepared for FirstLight. Midway, UT: Author.
- One goal is an assessment of management measures to minimize sediment releases from the upper reservoir during maintenance drawdowns. On July 15, 2011, FirstLight filed a *Sediment Management Plan* for the Northfield Mountain Project. The plan was filed in response to FERC's directive requiring measures to avoid or minimize entrainment of silt into the project's works during drawdown of the upper reservoir. The original plan has since been modified, in consultation with the MADEP and FERC, and calls for FirstLight to continuously record suspended sediment concentrations at the Route 10 Bridge and at the Northfield Mountain Project (both water used in pumping and generating). In addition, the plan called for annual bathymetric mapping of the upper reservoir to document changes in sediment accumulation or transport. At the end of each year FirstLight files with the FERC the study findings. The most recent report was filed with FERC on November 30, 2012. FirstLight is implementing the plan over a 4-year period, concluding with a final report to FERC by December 1, 2015. Based on the study findings, FirstLight will evaluate alternatives for sediment management in the upper reservoir during maintenance drawdowns. The suspended sediment concentration data and bathymetric surveys of the upper reservoir are available for this study.

Project Nexus (18 CFR § 5.11(d)(4))

The Connecticut River in the Turners Falls Impoundment is impacted by three hydroelectric projects which discharge or draw water from the river for hydropower generation. These Projects are (from downstream to upstream): the Turners Falls Project, Northfield Mountain Project, and Vernon Hydroelectric Project. All three Projects can operate as peaking facilities when flows are within the hydraulic capacity of the facilities, which can directly impact water level fluctuations in the Turners Falls Impoundment. When flows exceed the hydraulic capacity of the Vernon and Turners Falls Projects, the projects are operated as a run-of-river project.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Data Gathering and Background Mapping***Data Gathering*

Extensive research and data gathering efforts have been conducted within the Turners Falls Impoundment over the past several decades which will assist in this study. Existing data includes: hydrology, water elevation data, suspended sediment measurements, hydraulic modeling, and previous FRRs.

Background Mapping

Prior to conducting any field work, geo-referenced aerial imagery of the Turners Falls Impoundment will be developed in GIS and uploaded to pentop computer so that the geographic extents of active or recent bank erosion can be noted directly in the field. Also, separate GIS layers showing soil mapping and land use classification will be loaded along with the aerial imagery to allow personnel conducting the field assessment with quick reference data.

Task 2: Geomorphic Understanding of Connecticut River

It is important that the study include background of the geomorphic setting of the Connecticut River. This task would entail summarizing, as part of a larger report, the historic and modern geomorphology of the Connecticut River to provide readers with context. In addition, it would include background on the dynamic nature of alluvial rivers. More specifically, FirstLight will document causes of riverbank erosion that occur within a river corridor even if the river is not subject to rising and falling water levels due to hydropower operations. Causes of erosion include natural processes such as naturally high flow events as well as anthropogenic influences unrelated to hydropower operations.

Task 3: Evaluation of Water Elevation and Flow Data

The purpose of this task is to document the normal, maximum and minimum Turners Falls Impoundment elevation at four locations in the impoundment. This task is not intended to fully replace Objective (e) of the study that requests minimum, maximum and critical elevation data along the transects where active or recent erosion is field-documented. Rather it will provide a sense of the timing, magnitude, and duration of water level fluctuations that is occurring at four locations in the impoundment due to hydropower operations and naturally high flows.

As noted in the existing information section, FirstLight has hourly water elevation and flow data within the Turners Falls Impoundment for a 10-year period of record (2000-2009). Using the hourly data for this period of record, the following graphs and statistics will be developed for the four long-term water level recorders in the Turners Falls Impoundment:

- A table will be developed showing the monthly (and annual) minimum, maximum, median and average impoundment elevation at the four locations.
- Elevation duration curves have already been developed using the 2000-2009 data for the four long-term monitoring locations (see Section 4.3.1.6 and Appendix E of the PAD). The elevation duration curves provide background on the range of fluctuation.
- Ten graphs will be developed for each year between 2000 and 2009. Each graph will include the hourly water elevation for the four locations along with the flow estimated at the dam (which will

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

be a sum of the flow passed to the gatehouse and that passed below the Turners Falls Dam, as recorded on the log sheets). Also shown on these same graphs will be the flow as recorded at the USGS gage in Montague City, MA. This will provide background information on the relationship between the magnitude of streamflow and impoundment elevations.

In addition to water elevation data, the following flow information will be evaluated.

- Flow data from the Montague City USGS gage will be used to provide context on the magnitude, timing, frequency and duration of flows. Mean daily flows from this gage will be prorated, based on a ratio of drainage areas, to represent flow at Turners Falls Dam. As shown in the PAD, annual and monthly flow duration curves have been developed. FirstLight will develop a mean daily average annual hydrograph for the period after several USACE flood control facilities were constructed, to understand the magnitude of flow throughout the year, relative to the hydraulic capacity to the Project. In addition, using the post-USACE instantaneous peak flow data, a flood frequency analysis (Log Pearson Type III) will be conducted to predict the 2-, 10-, 50- and 100-year flood flows at the Turners Falls Dam. This information will be used for the hydraulic modeling assessment as described below.
- FirstLight records on an hourly basis the Vernon Dam discharge and the magnitude of generation or pumping (MW) at the Northfield Mountain Project. The Northfield pumping and generating data will be converted to flow based on MW versus cfs curve. For select periods of record representing high and low flows, weekly graphs (on an hourly basis) will display the flow at these two locations, along with the water elevation data recorded at the four long-term water monitoring gages for the same period of record. The purpose of this evaluation is to gain a better understanding of the contributions of water level fluctuations in the impoundment due to Vernon discharges, Northfield Mountain Project operations and both facilities.

Task 4: Hydraulic Model of Turners Falls Impoundment

A hydraulic model (HEC-RAS) of the Turners Falls Impoundment is available to assist with this study and can provide valuable information. In Objective (e), the precise elevation of the minimum, maximum and normal impoundment elevations, OHWM, and min/max daily ranges at those locations where erosion is occurring is sought. FirstLight believes that the hydraulic model, once calibrated to observed elevations as recorded at water level monitoring locations, could be used to predict the min/max, and normal pond elevations, recognizing that it will not fully replace field-based physical measurements.

As described in [Study No. 3.2.2 Hydraulic Study of Turners Falls Impoundment, Bypass Reach and below Cabot Station](#), FirstLight is proposing to calibrate the existing hydraulic model to observed Turners Falls Impoundment elevation data. Specifically, the goal is to simulate a few steady flow conditions (high flow and low flow) where flow throughout the length of the impoundment remains relatively stable and compare the model predicted elevation at the four long-term monitoring locations (and two gages installed in 2012) with observed elevation data. If the model reasonably reflects the observed water surface profile along the impoundment, it could be used to simulate a range of flows and range of downstream boundary conditions- in this case the water elevations at Turners Falls Dam.

In addition to the HEC-RAS model, the RIVER2D model yields information on the relationship between flow and near-bank velocity. RIVER2D modeling will be used to analyze near-bank velocity to determine shear stress along the bed and banks of the river. Analyzing near-bank velocity will be particularly useful in any future stabilization designs in areas identified in the field as active or recent bank erosion.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 5: Map and Describe Active or Recent Bank Erosion

FirstLight proposes to engage the following personal to conduct the study: a) a fluvial geomorphologist and professional engineer having specific expertise in hydrology, hydraulics, fluvial geomorphology, and sediment transport, b) a geotechnical professional engineer having specific experience with riverbank stabilization projects, c) an environmental scientist having experience with habitat needs for bank swallows and identifying “sensitive receptors, and d) other support staff. This field team will boat the Turners Falls Impoundment shoreline to conduct the following:

- Accurately map the start and end of any active or recent bank erosion sites (MADEP Objective (a)).
- Document any areas of bank erosion that have been the locus of prior bank stabilization and identify the method of stabilization implemented. The intent here is to learn from potential past stabilization projects that were unsuccessful such that future stabilization on river banks with similar features considers alternative methods (Objective (b)). A detailed review of all previously stabilized sites will be conducted. Specifically, several feet of shoreline has been stabilized over the decade using various techniques, some considered experimental. FirstLight wants to know what stabilization measures have or have not been successful. Based on this, it will help inform any potential future stabilization projects identified as part of this field study.
- Within the mapped areas of active or recent bank erosion, establish fixed, recoverable transects (Objective (c)). This will require establishing vertical and horizontal control at two benchmarks set back from the top of bank. By establishing monumented controls on the left and right banks, the endpoints will be fixed and, future cross-section surveys can be readily compared.
- Within the mapped areas of active or recent bank erosion, map land use practices that are directly observationally linked to erosion directly beneath and/or proximate to them (Objective (g)). Determine if the active or recent bank erosion is partially or fully attributable to land management practices adjacent to the river banks.
- Within the mapped areas of active or recent bank erosion, document any “sensitive receptors” such as specific locations of bank-nesting bird occurrences, “vegetated shallows” and other sensitive factors (Objective (h)). There may be instances where erosion is occurring, but stabilization may not be the best option if the eroded area provides particular types of high value habitat.
- At each of the transects within the active or recent bank erosion site, analyze the soils including: classification, structure, parent materials, texture, hydric regime, position on landscape, chemistry and most importantly engineering dynamics such as susceptibility to slope failure. Much of the information listed above can be obtained from previous sources; however, the fluvial geomorphologist and geotechnical engineer must collectively document observed soils in area of erosion (Objective (d)).

Task 6: Causes of Erosion

At each transect and erosion site documented above, the fluvial geomorphologist and geotechnical engineer will collectively evaluate the cause or causes of riverbank erosion. The erosion could be due to a single source or combination of sources. Potential causes of erosion could include:

- Hydraulic shear stress due to flowing water

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Water level fluctuations due to hydropower operations
- Boat and wind waves
- Land management practices
- Seepage and piping
- Freeze-thaw
- Ice or debris
- Animals such as nesting burrows
- Anthropogenic influences to the riparian zone (e.g., removal of riparian vegetation, cattle grazing to the river's edge, heavily traveled recreation trails)

In the report, the potential causes of erosion will be summarized. The fluvial geomorphologist and geotechnical engineer will determine if the susceptibility to bank failure is due to a) water level fluctuations due to hydropower operations, b) a combination of water level fluctuations due to hydropower operations in combination with other causes or c) other causes (Objective (f)).

The fluvial geomorphologist and geotechnical engineer will collectively look at all of the available data gathered above (plasticity index, soils maps, water level data, etc.) to make the determination as to whether the slope instability and/or erosion is caused (in whole or in combination with other factors) by hydropower operations.

Task 7. Identify Bank Stabilization Projects

Based on the information obtained for the field study and in-house work, FirstLight will identify bank stabilization projects within the Turners Falls Impoundment where a causal relationship to water level fluctuations due to hydropower operations can be determined.

Task 8: Upper Reservoir Drawdown Sediment Transport

As noted above under the Existing Information section, FirstLight is currently in the process of conducting a 4-year study as part of its *Sediment Management Plan*. The study includes a) continuously measuring suspended sediment concentrations at the Route 10 Bridge and at the Northfield Mountain Project (both water used in pumping and generating), and b) annual bathymetric mapping of the upper reservoir to document changes in sediment accumulation or transport. Suspended sediment monitoring is being performed year-round within the Northfield Mountain intake tunnel, and seasonally (spring-fall) in the Connecticut River. The most recent report was filed with FERC on November 30, 2012. Additional reports are anticipated to be filed on December 1 2013 and 2014. Per the *Sediment Management Plan* the final report will be filed with FERC by December 1, 2015. In the final report, FirstLight will evaluate practical strategies to minimize the release of accumulated sediment through the Northfield Mountain Project works during upper reservoir dewatering activities.

Task 9: Turners Falls Power Canal Sediment Transport

To drawdown the power canal, FirstLight uses the Cabot turbines; the Cabot spillway gates or log sluice are not used. FirstLight has not observed sediment releases due to using the Cabot turbines to lower the canal elevation. However, other stakeholders have requested a study to evaluate the impact of using the Cabot spillway on re-suspending sediment located in the Connecticut River – likely at the base of the Cabot spillway-- on sturgeon spawning habitat. Two separate studies addressing these issues are included as [Study No. 3.3.12 Evaluate Frequency and Impact of Emergency Water Control Gate Discharge Events and Bypass Flume Events on Shortnose Sturgeon Spawning and Rearing Habitat in the Tailrace and Downstream from Cabot Station](#) and [Study No. 3.3.18 Impacts of the Turners Falls Canal Drawdown on Fish Migration and Aquatic Organisms](#).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 10: Report

A comprehensive report will be developed and it is anticipated it will include the following sections:

- Executive Summary
- Introduction
- Geomorphology of the Connecticut River
- Evaluation of Water Level and Flow Data
- Evaluation of Boat Wakes
- Hydraulic Modeling
- Soil Mapping
- Field Study and Mapping
- Erosion Processes
- Causes of Erosion Attributable to FirstLight's Hydropower Operations
- Identify Bank Stabilization Project Attributable to FirstLight's Hydropower Operations
- Upper Reservoir *Sediment Management Plan* (note this study will not be completed until December 2015)

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is between approximately \$180,000 and \$220,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The cover letter outlines the PSP meeting schedule. The purpose of the Study Plan Meeting will be to resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. A portion of the field work may be conducted in 2013 along with the FRR. However, it is likely that the bulk of this study will be conducted during leaf-off in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.2 Water Resources*3.2.1 Water Quality Monitoring Study***General Description of Proposed Study**

Several stakeholder groups submitted a water quality study request to FirstLight. Water quality monitoring requests were received by MADEP, USFWS, CRWC, FRCOG, Town of Gill, LCCLC, VANR and NHDES.

The MADEP, USFWS, and CRWC study requests were similar and requested that the applicant conduct a water quality survey of the Turner Falls Impoundment, bypass reach, power canal, and tailrace reach in order to determine whether state water quality standards are being met under all currently-licensed operating conditions (i.e., during periods of generation and non-generation). MADEP, USFWS, and CRWC request that FirstLight collect continuous water temperature and dissolved oxygen (DO) data including biweekly DO and temperature profiles in the Connecticut River from April 1 through November 15, and monthly DO and temperature profiles within the upper reservoir from June through September. FirstLight is proposing continuous temperature and DO sampling, along with biweekly vertical profiles within the Connecticut River. As an alternative to periodic profile sampling in the upper reservoir, water quality from the Northfield Mountain Project discharge is proposed to be continuously monitored at the tailrace. These methods will be consistent with and therefore comparable to continuous data collected upstream and downstream of the tailrace, and can directly assess the impact of the discharge on water quality in the Connecticut River.

MADEP, USFWS, and CRWC also request that impoundment sediment adjacent to the Turners Falls Dam should be analyzed for metals and polychlorinated biphenyls (PCBs). As described in the existing information, benthic sediment was sampled in the Turners Falls Impoundment and upper reservoir in August 2010 as part of the USEPA consent order to inform FirstLight's dredging operations. The samples were analyzed for metals, organics, pesticides, and PCBs compared to MADEP regulatory standards. FirstLight is not proposing to conduct sediment sampling as part of this study.

Town of Gill, FRCOG, and LCCLC submitted similar requests for a water quality study, and included a request for monthly samples of total suspended solids and turbidity within the upper reservoir. FirstLight is not proposing to add turbidity or TSS to the water quality study plan because suspended sediment data are already being collected under FirstLight's *Sediment Management Plan* as described under Study No. [3.1.2](#) (see existing information section).

VANR and NHDES requested a more focused water quality study to determine if project operations are causing or contributing to violations of New Hampshire and/or Vermont state water quality standards. Their request for continuous data was linked to low flow periods and included additional parameters such as nutrients and chlorophyll a. FirstLight has proposed a sampling location in the Connecticut River upstream of the Massachusetts border which would be representative of inflow conditions to the Project. Sample parameters at this location will include temperature and DO, consistent with the sampling locations throughout the remainder of the Project study area. FirstLight is not proposing to collect data on nutrient parameters in the Connecticut River upstream of the Massachusetts border because these parameters are not consistent with MADEP's request and would not provide useful information if collected from a limited area.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The objectives of this study are to:

- Characterize water temperature and DO within the Turners Falls Impoundment, bypass channel, power canal, and below Cabot Station.
- Determine potential impacts of the Turners Falls Project and Northfield Mountain Project on water temperature and DO.
- Compare collected data with applicable state water quality standards.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The MADEP is responsible for issuing a water quality certification to FirstLight for the continued operation of the projects under Section 401 of the Clean Water Act. The MADEP has designated the Connecticut River as a Class B river for its entire length in Massachusetts, and is assigned the designated uses of habitat for fish, other aquatic life and wildlife, and for primary and secondary contact recreation, 314 CMR 4.05(3)(b). The anti-degradation provisions of 314 CMR 4.04 require protection of all existing and designated uses of water bodies, and maintenance of the level of water quality needed to protect those uses.

The USFWS water quality goals are to: 1) Protect, enhance, or restore diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats; and 2) Minimize current and potential negative project operation effects on water quality and aquatic habitat.

Part of the project area is within New Hampshire, and the NHDES establishes and administers surface water quality standards for New Hampshire; the Connecticut River within the New Hampshire portion of the project area is Class B water. The NHDES is responsible for ensuring that all state surface waters meet the water quality criteria for their designated classification, including existing and designated uses, and that the chemical, physical, and biological integrity of New Hampshire's surface waters is maintained. The Connecticut River is also classified by the state of Vermont as Class B cold water fish habitat, which should be managed to achieve and maintain a level of quality that fully supports aquatic biota and habitat, although criteria for Vermont are, in some cases, different than New Hampshire.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))*Existing Water Quality Data and Reports*

A multitude of federal, state and local organizations have studied the water quality of the Connecticut River in the vicinity of the Projects, including the following:

Carr, J. W. & Kennedy, L. E. (2008). *Connecticut River watershed 2003 water quality assessment report* (Rep. No. 34-AC-2). Worcester, MA: Massachusetts Department of Environmental Protection, Division of Watershed Management.

Need for Additional Water Quality Data

The state and federal resource agencies have requested a study of current water quality of the Connecticut River within the Project area. The results of the study should provide information sufficient to enable agencies to understand water quality conditions at the Project.

Sediment Contaminant Data

The resource agencies have requested that impoundment sediment adjacent to the Turners Falls Dam should be analyzed for metals and PCBs. FirstLight believes that recently collected data from the Turners Falls Impoundment contains sufficient data to address this issue.

Sediment was sampled in the Turners Falls Impoundment and upper reservoir in August 2010 as part of the USEPA consent order to inform FirstLight's dredging operations. The samples were analyzed for metals, organics, pesticides, and PCBs compared to MADEP regulatory standards. No detections were noted in any of the samples collected for PCBs and pesticides. Naturally occurring metals were detected in all of the samples at low levels below the residential soil standards, with the exception of nickel. Some nickel samples modestly exceeded the residential soil standards, but on average the nickel concentrations were below the residential soil standards. MADEP is currently seeking input on raising the regulatory standard for nickel. If the new standard is passed, the tested sediments will be well below the new nickel standard. In any event, it appears the nickel is naturally occurring and unrelated to project operations. If requested, the sediment sampling data will be made available.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Project Nexus (18 CFR § 5.11(d)(4))

Operation of the Turners Falls Project and Northfield Mountain Pumped Storage Project may directly impact water quality through the use of water for hydropower generation.

The investigation area includes the following:

- The 20-mile Turners Falls Impoundment extending from the base of Vernon Dam to the Turners Falls Dam.
- The Northfield Mountain Project Tailrace.
- The 2.7 mile long bypass from the Turners Falls Dam to the confluence with Cabot Station.
- The Turners Falls Power Canal.
- The Connecticut River downstream of Cabot Station.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

As recommended by the MADEP, water quality will be assessed in relation to project operations from spring through fall. If river flow and temperature conditions are representative of an “average” or “low” water year, then one year of data collection should be sufficient to perform the study. If conditions are not representative (i.e., a “wet” or cool year) then a second year of data collection may be necessary. Two types of water quality sampling will be performed, including: 1) continuous temperature and DO monitoring, and 2) periodic vertical profiles of temperature and DO.

Task 1: Develop Sampling Plan

MADEP states that a proposed water quality sampling plan is to be submitted to MADEP for approval prior to sampling and should be developed in consultation with MADEP and USFWS. Once the FERC Study Plan Determination is issued, which would detail the elements of the water quality study, FirstLight will prepare a detailed sampling plan consistent with FERC’s determination for review and approval by MADEP. The sampling plan will include quality assurances procedures to be followed during the study execution.

Task 2: Continuous Dissolved Oxygen and Temperature Monitoring

Temperature and DO will be continuously monitored every 15 minutes using *in situ* water quality meters at eight proposed locations within the project area ([Table 3.2.1-1](#)). The sampling locations are shown in [Figure 3.2.1-1](#), [Figure 3.2.1-2](#), and [Figure 3.2.1-3](#). Continuous water temperature will be collected from April 1 through November 15. Continuous DO measurements will be collected from the same locations during the summer low flow, high temperature period from June 1 through September 30. Continuous meters installed in impounded waters will be suspended from a surface buoy and deployed to 25% of the depth of the sampling location. In the bypass reach, canal, and downstream sampling locations, the meters will be installed mid-channel, mid-depth, as practical.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Spot measurements of DO and temperature will be taken during deployment, bi-weekly site visits, and upon retrieval to verify meter accuracy. Field notes will be collected and weather and flow⁷ conditions will be noted.

The water quality meters will be visited approximately bi-weekly, at which time data will be downloaded, the meter checked for calibration, and then re-deployed. The meter locations will be geo-referenced using GPS.

Task 3: DO and Temperature Profiles

To examine the vertical trends in temperature and DO within the Turners Falls Impoundment, a bi-weekly vertical profile of temperature and DO concentration will be recorded at the deepest location within the impoundment located downstream of the French King Gorge ([Figure 3.2.1-4](#)). Starting at the surface, measurements of temperature and DO will be collected at 1.0 meter depth increments; the depth of a thermocline or chemocline will be recorded. Bathymetric data indicate that this location is approximately 106 – 115 feet deep, depending on the water level within the impoundment. Vertical profiles will be collected bi-weekly starting in early April 2014 through mid November 2014, for a total of approximately 16 profiles, concurrent with Task 2.

Task 4: Report

A report will be prepared describing the monitoring methods and the results. An assessment of the potential effects of Turners Falls Project and Northfield Mountain Project operations on water quality will be discussed. For this assessment, FirstLight will provide hourly operations data during the duration of the continuous DO and temperature monitoring, including:

- Turners Falls Impoundment elevations as measured at the Vernon Tailrace, Northfield Mountain Tailrace, and Turners Falls Dam;
- Periods when Northfield Mountain is pumping, generating, or idle;
- Periods when Cabot Station and Station No. 1 are generating or idle;
- Discharges from Turners Falls Dam (spill), and;
- “Natural Routed Flow” through the Turners Falls Impoundment (estimate of flow at Turners Falls Dam).

The report will be submitted as part of the Initial Study Report as per the ILP process schedule. A tentative table of contents for the water quality report follows:

- Introduction
- Project Operations
- Hydrology and Weather Conditions
- Water Quality Monitoring Methods
- Water Quality Monitoring Results
- Discussion/Conclusions

⁷ Flow conditions in the Turners Falls Impoundment will be based on the estimated discharge from the Vernon Hydroelectric Project, intervening inflow from the Ashuelot and Millers River USGS gages, estimated discharge over the Turners Falls Dam, and the Connecticut River at Montague USGS gage.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Projects on water quality in the investigation area. The estimated cost for this one-year study is between approximately \$65,000 and \$85,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

A draft sampling plan developed under Task 1 will be provided to MADEP and USFWS in late 2013 once the FERC Study Plan Determination is issued. The sampling plan will provide more detail on the scope of work approved in the Study Plan Determination. Field work for this study is planned to occur from April through November 2014.

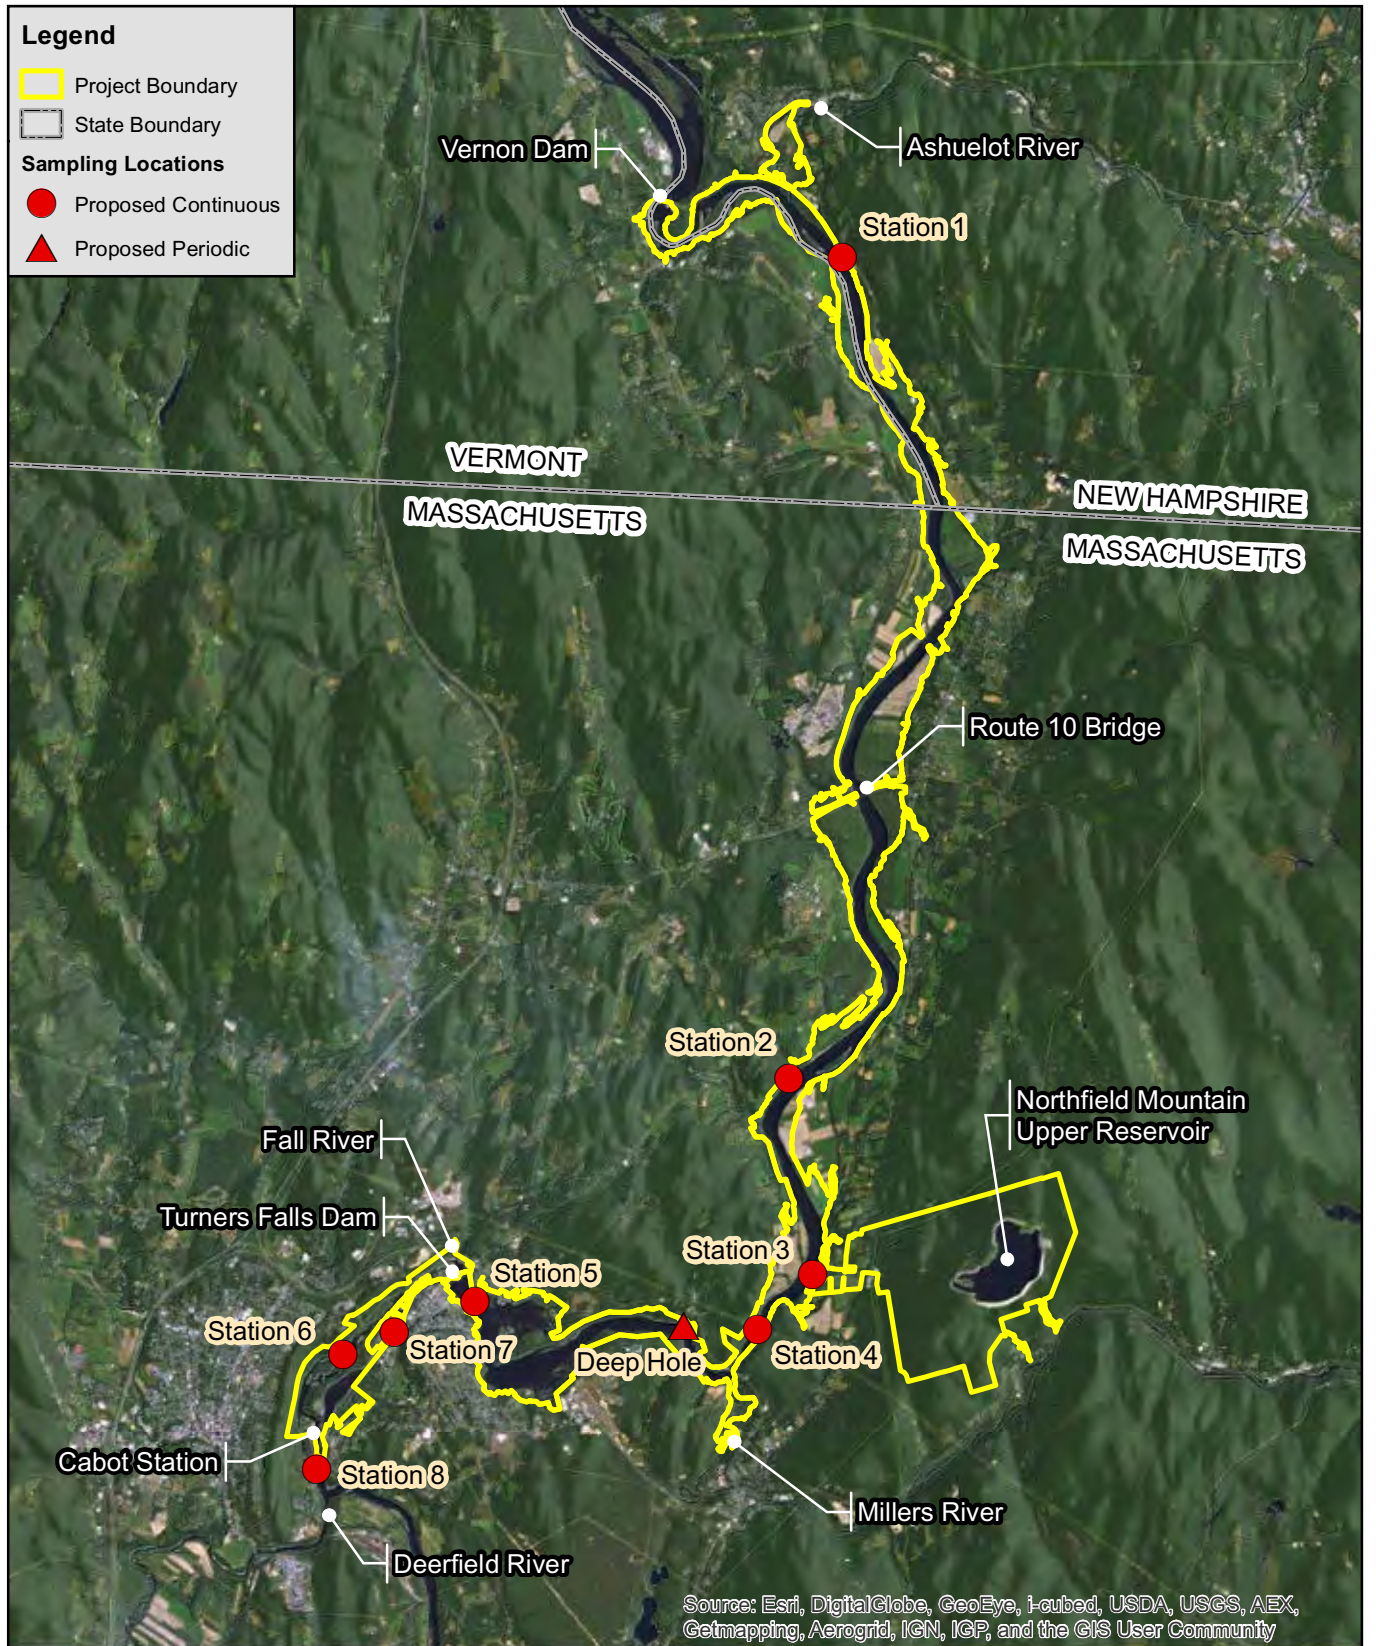

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.2.2 Hydraulic Study of Turners Falls Impoundment, Bypass Reach and below Cabot Station***General Description of Proposed Study***Background*

Numerous stakeholders requested studies to evaluate how water level fluctuations associated with the Turners Falls Project and Northfield Mountain Project impact various environmental, geologic and recreational resources. Those studies include:

- [Study No. 3.1.2](#) *Northfield Mountain/Turners Falls Operations Impact on Sediment Transport.*
- [Study No. 3.3.6](#) *Impact of Project Operations on Shad Spawning, Spawning Habitat and Egg Deposition in the area of the Northfield Mountain and Turners Falls Projects.*
- [Study No. 3.3.10](#) *Assess Operational Impacts on Emergence of State Listed Odonates in the Connecticut River.*
- [Study No. 3.3.13](#) *Impacts of the Turners Falls Project and Northfield Mountain Project Operations on Littoral Zone Fish Habitat and Spawning.*
- [Study No. 3.3.17](#) *Assess the Impacts of Project Operations of the Turners Falls Project and Northfield Mountain Project on Tributary and Backwater Area Access and Habitats.*
- [Study No. 3.5.1](#) *Baseline Inventory of Wetland, Riparian and Littoral Habitat in the Turners Falls Impoundment, and Assessment of Operational Impacts on Special-Status Species (includes rare plants and tiger beetles).*
- [Study No. 3.6.6](#) *Assessment of Effects of Project Operation on Recreation and Land Use.*

Water level fluctuations in the Turners Falls Impoundment can be a function of:

- Hydropower operations including peaking releases from the Vernon Hydroelectric Project, Northfield Mountain Project Pumping and Generating Cycles, and peaking operations at the Turner Falls Project.
- Motorized boat wakes.
- Natural flow variability. More specifically, water levels in the Turners Falls Impoundment will naturally rise and fall when flows exceed the hydraulic capacity of the hydropower facilities.

Water level fluctuations below Cabot Station can be a function of:

- Peaking operations at the Turners Falls Project when flow is within the hydraulic capacity of the facility.
- Peaking operations of several hydroelectric facilities on the Deerfield River.
- Motorized boat wakes.
- Natural flow variability, when the hydraulic capacity of the Turners Falls Project is exceeded.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Description

FirstLight proposes to develop a hydraulic model of the Turners Falls Impoundment⁸ and bypass reach, and of the Connecticut River below Cabot Station down to Holyoke Dam. The proposed hydraulic model is the one-dimensional HEC-RAS. The purpose of the hydraulic model is to determine for a given flow the corresponding water surface elevation (WSEL) at a given location within the river- typically at a transect that is included in the hydraulic model. In addition to predicting the WSEL for a given flow, the model also yields information on the river's depth and mean velocity at a given location (transect).

The HEC-RAS model can be run in both a steady state (flow is constant) and unsteady state (flow varies over time such as a hydrograph). FERC has requested that FirstLight develop an unsteady state HEC-RAS model in the Turners Falls Impoundment, bypass reach, power canal, and below Cabot Station to the upper limit of the Holyoke Impoundment. FirstLight proposes to develop two hydraulic models covering the a) Turners Falls Dam upstream to Vernon Dam and b) Turners Falls Dam downstream to Holyoke Dam. FirstLight maintains a nearly constant elevation in the power canal, except for periods of dewatering. The PAD contains supporting information on the limited fluctuation in power canal elevations (duration analysis of 10 years of hourly elevations). Given this, FirstLight does not believe a hydraulic model of the power canal is warranted.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The objectives of the hydraulic modeling study include:

- Provide WSEL (depth) and velocity information to help inform other environmental, geologic and recreation studies as listed above. For example, a study will be conducted to locate spawning substrate in the Turners Falls Impoundment. As part of that study, data will be collected on the depth to the spawning substrate. The hydraulic model will be used to assess whether Turners Falls Impoundment fluctuations could impact spawning substrate.
- An existing hydraulic model of the Turners Falls Impoundment will be used to determine the contribution of water level fluctuations in the Turners Falls Impoundment associated with operation of a) the Vernon Hydroelectric Project, b) the Northfield Mountain Project, c) the Turners Falls Project d) naturally occurring high flows, and e) all three projects operating collectively.
- An additional hydraulic model will be developed from the Turners Falls Dam downstream to Holyoke Dam to determine the contribution of water level fluctuations due to a) the Turners Falls Project, b) the Deerfield River Project, c) naturally occurring high flows and d) operations at Holyoke Dam. The rationale for extending the model to the Holyoke Dam is two fold. First the model requires a "downstream boundary condition". In this case the downstream boundary condition could be set at the FERC licensed range of allowable fluctuation at Holyoke Dam of 1.4 feet. The minimum and maximum FERC licensed fluctuation is 99.2 feet NGVD and 100.6 NGVD, respectively, at Holyoke Dam. The other reason for extending the model to Holyoke Dam is that operation (1.4 foot fluctuation) and hydraulic controls between Holyoke Dam and Rainbow Beach may influence water levels where the Puritan Tiger beetle is known to occur.

⁸ As noted later, FirstLight has already developed a hydraulic model of the Turners Falls Impoundment and filed on February 22, 2013 a report. Based on the model findings, FirstLight will propose to reduce the current Project Boundary.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

FERC and many resource agencies requested studies to evaluate the impact of project operations – specifically water elevation fluctuations -- on environmental, geologic and recreational resources. This hydraulic modeling study will provide information on the relationship between water level fluctuations and project operations.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))*Existing Information- Turners Falls Impoundment Hydraulic Model*

FirstLight has conducted numerous studies in the Turners Falls Impoundment related to erosion. One such study was conducted by Field Geology Services for use in studying fluvial processes/shoreline erosion in the Turners Falls Impoundment. To support the Field study, in 2006, a bathymetric map and two hydraulic models of the Turners Falls Impoundment were developed by Woodlot Alternatives Inc. (Woodlot) as summarized in the report entitled: *Connecticut River Hydraulic Analysis, Vernon Dam to Turners Falls Dam* (Woodlot, July 2007). The two hydraulic models include the one-dimensional HEC-RAS model, and the two-dimensional RIVER2D model.

As explained in FirstLight's report entitled: *Hydraulic Modeling Assessment of the Turners Falls Impoundment* (FirstLight, January 2013)⁹, FirstLight updated the existing HEC-RAS model for use in evaluating the upstream influence of the Turners Falls and Northfield Mountain Projects. As noted in the report, the influence ends approximately 9,000 feet below Vernon Dam and thus FirstLight is proposing to modify its Project boundary. No new additional information is needed to develop a hydraulic model of the Turners Falls Impoundment.

Existing Information- FirstLight's Water Level Recorders (River Stage)

River stage and flow data at various locations are available to help calibrate hydraulic models. The following sections summarize the data available to assist in hydraulic model calibration.

As noted in the PAD, FirstLight maintains WSEL monitors¹⁰ that record hourly at the following locations in the Turners Falls Impoundment:

- Immediately below Vernon Dam in the tailrace;
- In the Northfield Mountain tailrace;
- At the boat barrier located approximately 1,500 feet upstream of the Turners Falls Dam, and;
- At the Turners Falls Dam.

In addition to the long-term WSEL monitors noted above, for a portion of 2012, FirstLight maintained additional WSEL monitors as described in the PAD (Section 4.3.2.6 2012 Water Level Monitoring Baseline Study) at the following locations:

- In the Turners Falls Impoundment at the Route 10 Bridge and West Northfield Road;
- In the bypass channel above and below Station No. 1 (although the period of available data is limited due to vandalism);

⁹ This report was filed with FERC on February 22, 2013.

¹⁰ All of the FirstLight WSEL monitors are on the same vertical datum.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

- In the Connecticut River below Cabot Station at the Route 116 Bridge and across from Rainbow Beach.

Existing Information- Additional Flow and Water Elevation Data

There are four USGS gages in the Project area as listed in [Table 3.2.2-1](#).

Table 3.2.2-1: USGS Gages in Proximity to the Project Area

Gage No.	Gage Name	Drainage Area	Notes
01161000	Ashuelot River at Hinsdale, NH	420 mi ²	Drains into the Turners Falls Impoundment approximately 2.1 miles below Vernon Dam. A US Army Corps of Engineers Flood control facility is located above the gage (Surry Mountain Dam).
01166500	Millers River at Erving, MA	372 mi ²	Drains into the Turners Falls Impoundment immediately below the French King Bridge or approximately 3.9 miles upstream of Turners Falls Dam. A US Army Corps of Engineers Flood control facility is located above the gage (Birch Hill Dam).
01170000	Deerfield River near West Deerfield, MA	557 mi ²	Upstream of the gage are two seasonally operated reservoirs (Somerset and Harriman Reservoirs) and several peaking hydroelectric projects.
01170500	Connecticut River at Montague City, MA	7,860 mi ²	Located approximately 1,000 feet downstream from the Deerfield River confluence and approximately 0.74 miles below Cabot tailrace.

In addition to the USGS gages, FirstLight estimates flow at the following locations:

- Flow through the gatehouse is estimated based on the gate rating curves and head differential between the WSEL monitored at the Turners Falls Dam Impoundment elevation and Keith's Bridge located in the power canal.
- Flow passed by the Turners Falls Dam is estimated based on the Turners Falls Dam Impoundment elevation and the rating curves of the bascule and tainter gates.

Existing Hydraulic Model- Flood Insurance Studies

Flood Insurance Studies (FIS) of the Connecticut River are available through the Federal Emergency Management Agency (FEMA). The FIS is used to show the area of inundation under various flood flows such as the 100-year flood. FEMA developed hydraulic models of the Connecticut River, including the reach between Turners Falls Dam and Holyoke Dam. The most recent hydraulic modeling was conducted in the early 1980s and most likely used the USACE's HEC-2 model, the predecessor to HEC-RAS. FirstLight will secure the original HEC-2 input files, and convert them over to the HEC-RAS model to develop a hydraulic model of the reach between Turners Falls Dam and Holyoke Dam. As described below, FirstLight is proposing to reconstruct the hydraulic model developed by FEMA for use in this relicensing effort.

Instream Flow Study Transects

FirstLight is proposing to accelerate [Study No. 3.3.1 Conduct Instream Flow Habitat Assessments in the Bypass and below Cabot Station](#) such that field data is collected in 2013. As part of that study, FirstLight is collecting depth, velocity and WSEL data at transects locations yet to be determined. The field work

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

will also include measuring the total flow at these transects. The information collected for this study could be used to supplement the hydraulic model proposed below for the reach below Turners Falls Dam.

Upland Topography

To develop a hydraulic model, the topography of upland areas (river banks and floodplain) is needed, particularly when simulating flood flows. If upland information is needed, FirstLight will rely on the existing upland mapping obtained from USGS National Map Viewer- more specifically, the USGS 10 meter digital elevation model (DEM).

Need for Additional Information

As noted above, FirstLight needs to obtain the FIS hydraulic models developed for the reach between Turners Falls Dam and Holyoke Dam. The hydraulic models are likely in paper format and will require re-entering the data in HEC-RAS. FirstLight is proposing to re-develop the FIS hydraulic models in lieu of developing an original model for the following reasons a) the cost associated with conducting bathymetric mapping in the approximate 35-mile reach between Turners Falls Dam and Holyoke Dam is very expensive and b) re-developing the FIS hydraulic model will provide sufficient information on the relationship between river stage and flow and c) FirstLight installed water level monitors at two locations (Route 116 Bridge and at Rainbow Beach) in this reach during a portion of 2012 and there is also a long term water level monitor at the USGS gage at Montague. Thus, information is already available on the relationship between Turners Falls and Deerfield River Project operations and river stage.

Project Nexus (18 CFR § 5.11(d)(4))

Project operations result in water level fluctuations in the Turners Falls Impoundment and below Cabot Station. These fluctuations may have an impact on various environmental, geologic and recreational resources.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))*Connecticut River Hydraulic Model from Vernon Dam to Turners Falls Dam***Task 1: Update Turners Falls Impoundment HEC-RAS model**

The existing Turners Falls Impoundment HEC-RAS model does not include major tributary inflows, namely the Ashuelot and Millers Rivers. To date, the HEC-RAS model has been used to predict the WSEL under a constant (steady) flow throughout the length of the impoundment- meaning the flow at the Vernon tailrace is the same as the flow at Turners Falls Dam. FERC has requested that the HEC-RAS hydraulic model be operated in an unsteady mode allowing for time varying flow. To simulate time varying flow, the model would require updates including the Vernon Hydroelectric Project discharge hydrograph and flows recorded at the Ashuelot and Millers Rivers USGS gages. In addition, the model will require updates to reflect when water is leaving the impoundment (Northfield pumping) and when water is added to the impoundment (Northfield generating).

FirstLight records on its log sheets hourly Vernon discharges, and Ashuelot and Millers River flows based on the USGS gages to estimate the naturally routed flow through the impoundment. In addition, the log sheets include the hourly magnitude (MW) of pumping and generating, which can be converted to flow using a ratio of design flow (cfs) to capacity (kW) for both pumping and generating (see page 4-33 of PAD).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Model Calibration

The hydraulic model would be calibrated to measured WSELs (Vernon tailrace, Northfield tailrace, and Turners Falls Dam) in the Turners Falls Impoundment for select flows. The HEC-RAS model will be operated as steady state with no pumping or generating occurring at Northfield such that flow conditions through the length of the impoundment are relatively steady for several hours. FirstLight has developed a relationship between flow and travel time (in hours) through the Turners Falls Impoundment. As a guide, at flows less than 20,000 cfs, the travel time is approximately 10 hours, and at flows near 80,000 cfs, the travel time is approximately 4 hours. Ideal conditions would be if discharges from Vernon are relatively constant for 12+ hours and Northfield is idle. The HEC-RAS model will be operated for a given flow and the WSELs measured at FirstLight monitoring locations will be compared to the model results. If needed, calibration will consist of adjusting Manning n values (roughness) or adjusting contraction/expansion coefficients within reasonable measures such that the measured and modeled WSELs are reasonably close.

Task 3: Unsteady Flow Model

Once the model is calibrated, it will be updated to simulate unsteady flow conditions. In this case, time varying flows will be simulated to determine changes in the WSEL at select locations in the Turners Falls Impoundment. To evaluate the contribution of water level fluctuations from various sources sensitivity analyses will be conducted. For example, a time varying discharge hydrograph from Vernon Station will be simulated while the Northfield Mountain Project remains idle to determine the contribution of water level fluctuations caused by Vernon Station. Similarly, a constant discharge hydrograph from Vernon Station will be simulated while the Northfield Mountain Project is operated as a pump or generator. Finally, other combinations of flows and operating conditions at the facilities will be evaluated. Output from the model will include WSEL and average channel velocities¹¹ for various flows simulated.

*Connecticut River Hydraulic Model from Turners Falls Dam to Holyoke Dam*Task 4. Contact FEMA and Obtain FIS Hydraulic Model

FirstLight will contact FEMA to obtain the FIS studies in those communities located between Turners Falls Dam and Holyoke Dam. Experience indicates that FIS studies conducted in the early 1980s were conducted using HEC-2, the predecessor to HEC-RAS. Note that the energy equations and computations between both models are the same, although HEC-RAS has more features and graphical displays. It is likely that the original HEC-2 input files are retained on microfiche. FirstLight will obtain the microfiche, and print out the input files. The input files contain the following information which will be entered into the HEC-RAS model:

- Channel transect coordinates.
- Mannings “n” values.
- Distance between transects.
- Bridge geometry¹².
- Expansion and contraction coefficients.
- Flood flows.

¹¹ Note that HEC-RAS model can calculate velocities laterally across the transect based on conveyance. These velocities will reflect average velocities for the transect.

¹² FirstLight will contact MassDOT to obtain any bridge information (pier shape, low chord, etc.) to determine if the bridge data contained in the HEC-2 model reflects today’s bridge geometry.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 5. Development of HEC-RAS model and Model Calibration

The data on the printed input files will be entered into the HEC-RAS model. The FIS will be re-constructed and validated by simulating the 100-year flood flow to ensure that the HEC-RAS model output—specifically, the water surface profile—reasonably matches that shown in the FIS. Once the model reasonably matches the 100-year water surface profile, it will be used to simulate various steady state flows similar to the methodology described above. For example, a relatively constant flow throughout the 35-mile long reach experienced during the period the FirstLight has WSEL data at the Route 116 Bridge and Rainbow Beach will be simulated. The measured WSEL at these two locations and at the Montague USGS gage will be compared to that predicted by the model. Similar to above, the model will be calibrated by adjusting Manning n values or expansion/contraction coefficients within reasonable measures.

As part of [Study No. 3.3.1](#) *Conduct Instream Flow Habitat Assessments in the Bypass Reach and below Cabot Station*, FirstLight will be obtaining additional transect and geomorphic data to support this study. For those locations where transects are obtained, they too will be added into the HEC-RAS model. Also, [Study No. 3.3.1](#) requires collecting stage discharge relationships at transects (final locations yet to be determined) that will be added into the model. These data, along with the WSEL monitoring data obtained in 2012 will be used to calibrate the model to observed WSELs.

Task 6. Unsteady Flow Model

Similar to Task 2 above, once the model is calibrated, it will be updated to simulate unsteady flow conditions. Time varying flows will be simulated to determine changes in the WSEL at select locations in the 35-mile long reach. To evaluate the contribution of water level fluctuations from various sources sensitivity analyses will be conducted. In this case, water level fluctuations could be a function of, or influenced by, the Turners Falls Project, the Deerfield River Project, and the WSEL maintained at Holyoke Dam (1.4 foot fluctuation permitted). For example, a time varying discharge hydrograph from the Turners Falls Project will be simulated while flows from the Deerfield River remain stable to determine the contribution of water level fluctuations caused by the Turners Falls Project. Similarly, a constant discharge hydrograph from the Turners Falls Project will be simulated while the Deerfield River Project discharges vary. Finally, other combinations of flows, operating conditions at the Turners Falls and Deerfield River Project, and starting downstream boundary conditions (Holyoke Dam elevation) will be evaluated. Output from the model will include WSEL and average channel velocities for various flows.

Task 7: Report

A comprehensive report will be developed to include the following:

- Introduction
- Project Layout
- Summary of Existing Data
 - Existing USGS Gage Flow
 - Flow in Power Canal and Passed at Turners Falls Dam
 - Water Level Recorders
- Hydraulic Modeling
 - Connecticut River between Vernon and Turners Falls Dams
 - Connecticut River between Turners Falls and Holyoke Dams
 - Steady State Modeling
 - Calibration

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Unsteady State Modeling
- Findings
- References

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Projects on water level fluctuations. The HEC-RAS model of the Connecticut River between the Vernon and Turners Falls Dams is essentially complete with the exception of calibrating to observed WSELs and simulating unsteady flow conditions. More time will be spent developing the HEC-RAS model of the Connecticut River between Turners Falls and Holyoke Dams. The estimated cost of this study is between \$70,000 and \$90,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

Given that this study is not dependent on field work (with the exception of addition in transects from the instream flow study) it could be started after FERC issues its study plan determination letter.

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013, with detailed study plan specific meeting thereafter as noted in the cover letter. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.3 Fish and Aquatic Resources**3.3.1 Conduct Instream Flow Habitat Assessments in the Bypass Reach and below Cabot Station****General Description of Proposed Study**

USFWS, NOAA, MDFW, NHFG, CRWC, TNC and TU requested that a habitat-based field study, such as the Instream Flow Incremental Methodology (IFIM) be conducted in the Turners Falls bypass reach and in the Connecticut River downstream of Cabot Station. An IFIM study is proposed to quantify the relationship between station operation and aquatic habitat.

FirstLight is proposing to conduct this study in 2013, in advance of the typical two-year study time frame allowed by the ILP (2014-2015).

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The purpose of the study is to assess the potential effects of the range of discharges from Turners Falls Dam, Station No. 1, and Cabot Station on wetted area and aquatic habitat suitability in the Connecticut River between Turners Falls Dam and Cabot Station (the bypass reach) and below Cabot Station downstream to the Route 116 Bridge in Sunderland, MA.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals identified are to:

- Determine an appropriate flow regime that will protect and enhance the aquatic resources in the bypassed reach between Turners Falls Dam and the Cabot Station discharge.
- Determine an appropriate flow regime that will protect and enhance the aquatic resources from the Cabot tailrace of the Turners Falls Project downstream to the Route 116 Bridge in Sunderland, MA.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

In 2012, aquatic habitat mapping and water level monitoring were conducted at the following locations:

Habitat Mapping

- In the Connecticut River bypass reach from Turners Fall Dam to Cabot Station, and;
- In the Connecticut River from Cabot Station approximately 30 miles downstream to a natural hydraulic control located in the vicinity of the Dinosaur Footprints Reservoir (see [Figure 3.3.1-1](#)).

Water Level Recorders

- From approximately late April 2012 through mid August 2012, FirstLight installed continuously recording water level loggers that measured the change in water elevations. Two loggers were placed in the bypass reach from Turners Falls Dam to below Cabot Station (although vandalism was an issue), and three loggers were placed below Cabot Station (at the existing Montague

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

USGS gage, at the Route 116 Bridge in Sunderland, and at Rainbow Beach in Northampton). See [Figure 3.3.1-2](#) for a map showing the logger locations. All loggers were surveyed to a common datum to allow for comparison. Appendix E of the PAD contains weekly plots of the data obtained from these water level loggers.

The 2012 aquatic habitat mapping report entitled “*Aquatic Mesohabitat Assessment and Mapping*” prepared by FirstLight (2012) was filed with FERC on January 8, 2013. It also can be found on FirstLight’s relicensing website at <http://www.northfieldrelicensing.com>.

Project Nexus (18 CFR § 5.11(d)(4))

Per the FERC license, FirstLight is required to release a continuous minimum flow of 1,433 cfs or inflow, whichever is less, below the Turners Falls Project year-round. FirstLight typically maintains the minimum flow requirement through discharges at Cabot Station and/or Station No. 1.

Per the FERC license, a continuous minimum flow of 200 cfs is maintained in the Connecticut River bypass reach starting on May 1, and increases to 400 cfs when fish passage starts by releasing flow through a bascule gate¹³. The 400 cfs continuous minimum flow is provided through July 15, unless the upstream fish passage season has concluded early in which case the 400 cfs flow is reduced to 120 cfs to protect shortnose sturgeon. A 120 cfs continuous minimum flow is maintained in the bypass reach from the date the fishways are closed (or by July 16) until the river temperature drops below 7°C, which typically occurs around November 15th. The 120 cfs flow release was determined in 1993 in consultation with MADFW, NMFS, and USFWS to ensure that an adequate zone of passage exists in the reach during the months when sturgeon may be present and require volitional movement.

Approximately 87% of the inflow to the Turners Falls Impoundment is controlled by discharges from the Vernon Hydroelectric Project. The majority of the remaining 13% percent of inflow to the Turners Falls Impoundment is from the Ashuelot and Millers Rivers. The Vernon Hydroelectric Project has a hydraulic capacity of 17,130 cfs, while the hydraulic capacity of the Turners Falls Project (Cabot and Station No. 1 combined) is approximately 15,938 cfs. When flows are within the hydraulic capacity of the Vernon Hydroelectric Project, inflows to the Turners Falls Impoundment reflect peaking discharges.

FirstLight operates the Turners Falls Project as a peaking facility when flows are in the hydraulic range of the Turners Falls Project and as a run-of-river facility when flows exceed the hydraulic capacity of the Turners Falls Project (15,938 cfs). The Northfield Mountain Project operates as a peaking project.

Project operations have the potential to influence aquatic habitat in the bypass reach and below Cabot Station. Based on water level monitoring studies conducted in 2012, it appears that hydraulic effects of peaking operations may extend downstream to Rainbow Beach, approximately 25 miles below Cabot Station; however, significant habitat effects attenuate rapidly below Sunderland, MA.

The Connecticut River immediately below Cabot Station has been identified as a major spawning area and overwintering area for the Endangered Species Act (ESA)-listed shortnose sturgeon. Other diadromous species such as American shad adults and juveniles, seasonally utilize habitat in this vicinity for spawning and rearing. American eels and Atlantic salmon seasonally rely on this reach as a migration corridor.

¹³ The bascule gate used to pass the minimum flow is located at the Turners Falls Dam and is the one closest to the gatehouse.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Background**

The scope of this study is to quantify the effects of Project flows on aquatic habitat suitability in the Connecticut River for the aquatic community and its managed fish resources, potentially including diadromous and resident fish species, and aquatic invertebrates. These data will then be used in conjunction with hydrologic, operational and other models to evaluate the costs and benefits of potentially providing alternate habitat-based flows to the Connecticut River in the study area.

Task 1: Consult with Agencies and Interested Stakeholders to Determine Study Area, Study Reaches, and Habitat Suitability Index Curves*Study Area*

The Connecticut River segment between the Turners Falls Dam and the Route 116 Sunderland Bridge ([Figure 3.3.1-1](#)) was identified by the applicable state and federal fishery agencies (agencies) as the study area for purposes of the habitat based study. Flow in this reach is cumulatively influenced by discharges from upstream tributaries, hydroelectric projects in the upper Connecticut River, the Turners Falls Project and the Northfield Mountain Project. Additional discharges to the study area immediately below Cabot Station include the Deerfield River, which contributes approximately 665 square miles (mi²) of additional drainage area. The Deerfield River includes several FERC-licensed hydroelectric projects operating as peaking facilities and two seasonal regulated storage reservoirs- Somerset and Harriman Reservoirs in Vermont.

An IFIM study is proposed to develop an understanding of key habitat suitability-flow relationships in the study area. This may be quantified by models such as Physical Habitat Simulation (PHABSIM) or its equivalent. The model(s) will be used to simulate habitat suitability at various flow increments representing selected anadromous and resident fish species, and aquatic biota (i.e., macroinvertebrates). One-dimensional (transect-based) and/or two dimensional (finite elements-based) hydraulic models are required to simulate river channel hydraulics in various areas of interest.

Consistent with IFIM protocol, a study team comprised of licensee and qualified fishery biologists will be formed for the purpose of making technical decisions regarding input parameters and review of study output. Specifically, that study team will collaboratively designate:

1. specific spatial and temporal habitat management goals,
2. boundaries of the study area and reaches,
3. locations of specific representative or critical study sites, and study site transects,
4. Habitat Suitability Index (HSI) criteria for applicable species and lifestages, and
5. calibration flows and range of flows to be assessed.

Study Reaches and Transect Selection (1-D and 2-D Modeling)

The proposed study methodology involves a phased approach beginning with review of recently-mapped mesohabitat distribution throughout the study area. The mapping and characterization of aquatic mesohabitat provides essential information regarding the extent, location, and composition of aquatic habitats that may be affected by Project operation.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study reach boundaries are typically placed at significant breaks in geomorphic, hydrologic or habitat use in the study area (Bovee et al., 1998)¹⁴. The study team will consult to define study reaches and select applicable study sites within each reach, as well as cell boundaries and transects in areas of 1-dimensional (1-D) modeling within each study site.

Study sites may represent typical and/or unique but critical habitats within each reach. For 1-D model applications, the study team will select upstream and downstream cell boundaries within each study site based on localized observed shifts in stream width, cover, substrate, and hydraulics. The field crew will subsequently locate a transect within each longitudinal cell defined by the boundaries.

Based on preliminary discussions with the agencies, due to complex flow patterns near the islands above the Cabot tailrace, a 2-D model is proposed from the upstream end of the Rawson Island to just below the Deerfield River confluence (specifically at the USGS Gage at Montague).

Project operations and configuration affect flow and habitat in distinct ways. For this reason, four study reaches are recommended for modeling purposes (see an overview of locations in [Figure 3.3.1-1](#) and a close-up of the bypass reach area in [Figure 3.3.1-3](#)). The following study reaches are proposed:

- **Reach 1. Upper Bypass Reach.** This reach is approximately one mile long extending from the Turners Falls Dam downstream to the confluence with the Station No. 1 tailrace. Habitat and flow in this reach are influenced by discharges from the Turners Falls Dam, attraction and fishway flows for the Spillway fish ladder and the Fall River (see [Figure 3.3.1-3](#) for location). Stream channel structure and geomorphology are controlled primarily by bedrock. From the Turners Falls Dam to the just below the Fall River confluence, the bypass channel is quite wide and the thalweg poorly defined, before starting to narrow just upstream of the Station No.1 tailrace. Mesohabitat in this reach includes pool, run and riffle with bedrock overlaid with rubble and cobble substrates.
- **Reach 2. Lower Bypass Reach.** This reach is approximately two miles long extending from the Station No. 1 tailrace downstream, terminating at an island complex and a geological feature including a natural ledge drop known as “Rock Dam”. Flow is influenced by both the net discharge from Reach 1, as well as Station No. 1, when generating. Stream channel structure is controlled primarily by bedrock. Reach 2 channel morphology is relatively well defined, and includes pool, run and riffle mesohabitats with bedrock overlaid with rubble and cobble substrates.
- **Reach 3. Tailrace Reach.** The tailrace reach extends from below the Rock Dam/Rawson Island complex downstream to the USGS Gage No. 01170500 at Montague, which includes the confluence with the Deerfield River. Habitat in this reach is influenced by flows from Reaches 1 and 2 as well as generation at Cabot Station including backwatering around the island complex upstream to the toe of Rock Dam. Stream channel structure is comprised of alluvial deposits, including a series of island and split channel complexes both upstream, across, and downstream from the Cabot Station powerhouse. Hydraulic effects are complex, and include backwatering from Cabot Station upstream to Rock Dam as well as flow between islands. Habitat is primarily riffle and run; substrate is dominated by gravel bars and cobble, and includes ledge outcrops at the General Pierce Bridge area.
- **Reach 4. Downstream Reach.** This reach extends from the Montague gage to the Sunderland Bridge (Route 116), which is where backwater influence of the Holyoke Project impoundment

¹⁴ Differences in slope, geomorphology, substrate, and flow influence, suggest that four reaches may be justifiable.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

generally is detected. Flow is primarily influenced by outflow from Reaches 1-3 and the Deerfield River. This section of river is alluvial and low gradient, with well defined channel and embankments, and repeating patterns of pool and run habitat. Substrate varies but is dominated by cobble, gravel and fines.

- **Reach 5.** This section of the river extends from the Project Boundary at the Route 116 Bridge to a natural hydraulic control located in the vicinity of Dinosaur Footprints Reservation. It is a low gradient, alluvial reach with limited mesohabitat variability and in many cases very gradual or subtle transitions from one mesohabitat type to the next contiguous type. Over 75% of the mesohabitat in this reach is comprised of run.

Habitat Suitability Index Criteria

FirstLight anticipates the use of habitat suitability index curves (HSI) curves adopted primarily from those previously used in support of recent PHABSIM models conducted at study sites with similar geomorphic and ecoregion characteristics. HSI curves will be obtained and reviewed for applicability, discussed, modified as necessary and approved by the study team. Based on preliminary consultation with agencies, FirstLight proposes to evaluate the following HSI criteria:

Study Reach	Species	Lifestage/criteria
Reach 1 and 2	American shad	zone of passage
	white sucker	zone of passage
	white sucker	spawning, fry, juvenile, adult
	fallfish	spawning, fry, juvenile, adult
	freshwater mussels	host fish zone of passage
	benthic macroinvertebrate	larvae
Reach 3	American shad	spawning and incubation
	shortnose sturgeon	spawning and incubation, overwintering juvenile, overwintering adult
	sea lamprey	spawning and incubation
Reach 4	American shad	spawning and incubation
	sea lamprey	spawning and incubation
	white sucker	spawning, fry, juvenile, adult
	fallfish	spawning, fry, juvenile, adult
	benthic macroinvertebrate	larvae
Reach 5	shortnose sturgeon	Overwintering juvenile, overwintering adult
	To be determined	

[Attachment A](#) includes a draft set of proposed HSI curves. [Table 3.3.1-1](#) includes the proposed velocity, depth and substrate habitat suitability criteria and sources. Note that for the American shad and shortnose sturgeon, the HSI curves were obtained from the recent Conowingo Hydroelectric Project relicensing on the Susquehanna River in Maryland. The HSI curves for the remaining species below may require further refinement.

Task 2: Field Data Collection

The second phase will quantify habitat-discharge relationships for selected species and lifestages in the study area, using standard PHABSIM data collection and flow modeling procedures ([Bovee, 1982](#); [Bovee et al., 1998](#)). The modeling approach dictates what field data collection is necessary as explained below.

Data Collection in Reaches 1, 2, and 4 (1-D modeling)

It appears that a 1-D model approach using PHABSIM is suitable for Reaches 1¹⁵, 2, and 4. A 1-D modeling approach will be based on hydraulic data developed from cross-sectional depth, velocity, and substrate measurements following Milhouse et al. ([1989](#)), using PHABSIM for Windows (V 1.5.1), developed by the USFWS and distributed by the USGS Fort Collins (CO) Science Center.

The location of each transect will be field blazed with flagging or other appropriate means. Each study site and cell boundary will be mapped sufficiently to quantify the area represented by each transect. The transect headpin and tailpins will be located at or above the top-of-bank elevation, and secured by steel rebar or other similar means. Measuring tapes accurate to 0.1 ft will be secured at each transect to enable repeat field measurements to occur at specific stream loci¹⁶. Stream bed and water elevations tied to a known datum will be surveyed to the nearest 0.1 ft using standard optical surveying instrumentation and methods.

Depth, velocity, and substrate data will be gathered at intervals (verticals) along each transect. Each vertical will be located to the nearest 0.1 ft wherever an observed shift in depth or substrate/cover occurs. Between 20 and 99 verticals per transect will be established as necessary on each transect. Verticals will be positioned so that no more than 10% of the discharge passes between any pair, to enhance hydraulic model calibration. A staff gage will be located in each study site, and monitored at the beginning and end of each set of hydraulic measurements to verify stable flow during measurements. If flow is found to be insufficiently stable, the related data will be discarded and re-measured once stable flow is established.

Mean column velocity will be measured to the nearest 0.1 ft/second with either a calibrated electronic velocity meter mounted on a top-setting wading rod, or alternatively an Acoustic-Doppler Current Profiler (ADCP) transducer. In water less than 2.5 ft depth, velocity measurements will be made at 0.6 of total depth (measured from the water surface); at greater depths, paired measurements will be made at 0.2 and 0.8 of total depth and averaged.

Each calibration flow will be provided by scheduled releases from the Project via unit operation or in the case of the bypass reach through gate settings. Turbine rating curves, USGS gages, and study-site field gaging will be collectively used to estimate each calibration flow release. The 1-D hydraulic model will be developed from measurements gathered at a minimum of three calibration flows to facilitate extrapolation of hydraulic data across the range of interest. To accomplish calibration, a full set of depth, velocity and water surface elevation (WSEL) data will be gathered at the intermediate flow, and WSEL will be measured at each transect for the low and high flows to calibrate the hydraulic models. At transects with complex hydraulics such as riffles, and/or sites with unusual backwatering or eddy effects,

¹⁵ A 2D model may be required for a portion of the uppermost section of the bypass reach if specific habitat targets are identified in this locale.

¹⁶ Supplemental transects may be located as needed to record water surface and bed elevation data at hydraulic controls to establish backwatering parameters necessary for hydraulic modeling.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

supplemental velocity data may also be gathered at the low calibration flow. This will be determined in the field on a case-by-case basis.

For the 1-D model, each calibration flow should ideally be broadly separated to provide a suitable stage-discharge curve for the hydraulic model. The general rule of thumb is the hydraulic model, and hence depths and velocities, can be extrapolated from 40-250% of the calibration (measured) flow. Thus, the following calibration flows and associated flow ranges can be evaluated in the 1-D and 2-D hydraulic models. The suggested calibration flows are listed below.

Reach(es)	Calibration Flow	Targeted Extrapolated Flow Range	WSEL only or Both (WSEL and velocity measurements)
1, 2, *4	300 cfs (low flow)	120 cfs to 750 cfs	Both, at complex hydraulics such as riffles
	900 cfs (intermediate flow)	360 cfs to 2,200 cfs	Both
	2,500 cfs (high flow)	1,000 cfs to 6300 cfs	WSEL
3	2,500-9,000 cfs	1,433 cfs to 22,500 cfs	Both

*Reach 4 calibration flows will be higher due to the contribution of the Deerfield River. FirstLight will work with TransCanada (Licensee of the Deerfield River Hydroelectric Project) during the data collection in Reach 4 to maintain a steady continuous flow from the Deerfield River.

Data Collection in Reach 3(2-D Modeling)

A two dimensional (2-D) approach will best represent hydraulics in Reach 3 due to the complex channel characteristics and hydraulics.

For the 2-D model, a single calibration flow is required; the exact flow required is not critical but should be one that is representative of hydraulic conditions intermediate throughout the range of flows of interest, including “typical” generating from Cabot Station and an intermediate discharge through the bypass reach. The need for any additional calibration flow data will be evaluated on a case-by-case basis.

A 2-D model will be developed using a combination of terrain (LIDAR and/or 10m DEM, depending on availability) and bathymetric data. This will include a WSEL survey, and flow gaging at the inlet and/or outlet of the study site. To the extent possible, bathymetric data will be provisionally assembled from existing sources including past modeling, surveys, bridges, Project related information, and fishing/recreation maps. It is likely that additional bathymetric data will need to be collected to supplement the existing data coverage. These will be obtained through a combination of depth sounding and RTK-GPS (Real Time Kinematic), as required. In addition, it is expected that a high-level of bathymetric mapping will be obtained in the vicinity of the Cabot tailrace and existing fishway entrance in case future computation fluid dynamic (CFD) modeling are needed in the future.

Task 3: Hydraulic Modeling (Reaches 1-4)

Model boundary conditions (input values for generation at Cabot and Station No. 1, river discharge, spill at Turners Falls Dam, and tributary inflows) will be obtained from observed flow and release records. Modeling scenarios will be developed and run in “steady state” mode to produce data required to support the PHABSIM analyses including water profiles, wetted area, depth and velocity at flow increments of interest.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

1-D hydraulic modeling will be accomplished by calibration (correlating each surveyed WSEL set with discharge to develop a stage-discharge relationship for each transect). PHABSIM uses STGQ, MANSQ and WSP models to predict water surface elevations at various calibration flows. It then uses the VELSIM model to predict cellular water velocities based on the calibration dataset(s). The model is calibrated by comparing simulated hydraulics to empirical measurements taken at the calibration flows. Coefficients such as relative stream channel roughness (commonly referred to as Mannings n) are then iteratively adjusted as needed to optimize model accuracy across the full flow range. Once this relationship is established, the model then calculates additional WSELs at other flow increments, and adjusts velocities obtained at calibration flows to other flow increments of interest for which defined water stages have been calculated.

2-D hydraulic modeling, while similar in many ways to 1-D modeling, requires an initial phase of developing and testing of the model grid-space and arrangement. The process is iterative, with a goal of finding the best balance of model stability, accuracy, and performance. This will occur at a single test condition that represents a fairly common flow, including representative hydraulics, and has sufficient supporting input data (e.g., most observations).

Following development and testing of the model grid, the model will then be calibrated and verified. The most common approach for calibration is to provide a discharge value as the upstream boundary condition while the downstream boundary relies on the measured WSEL. Measured WSELs at the survey transects will be used to directly calibrate to a specific steady flow analysis scenario. Calibration is achieved by adjusting the resistance terms in the model to provide predicted WSELs that best match measured WSELs, for a given discharge. Model verification will be conducted by running the calibrated model for other measured flow conditions and comparing the model-predicted results to the independent measured values.

Task 4: Habitat Modeling (Reaches 1-4)

Once the hydraulic model is calibrated, habitat suitability at each flow increment of interest will be quantified by combining the HSI and hydraulic model data using the HABTAE and supporting programs within PHABSIM. These output units of Weighted Usable Area (WUA) for each transect at each flow increment, for each species and lifestage. WUA is an abstract habitat suitability index generated from units of square feet of optimal habitat available per 1,000 feet of represented stream length. The habitat suitability-flow curves across the flow range for all transects in a given study site are then weighted and summed at the study reach level, according to actual linear stream length that each site represents, as mapped in the field.

Task 5: Habitat Time Series (Reaches 3-4)

The WUA information (habitat versus flow) will be merged with HEC-ResSim model results (see [Study No. 3.8.1](#), *Evaluate the Impact of Current and Potential Future Modes of Operation on Flow, Water Elevation and Hydropower Generation*) for Reaches 3 and 4. Specifically, FirstLight will use the hourly discharge hydrograph(s) below Cabot Station from the HEC-ResSim model. The discharge hydrograph from the model will be merged with the Weighted Usable Area versus flow curves from the IFIM study to yield habitat time series. All habitat time series analysis will rely on flow data from the baseline model, which will be used a basis of comparison. Habitat time series will be developed from any alternative modes of operation using the HEC-ResSim discharge data, which again will be compared to the baseline model habitat time series. The alternative operation scenarios will be developed in consultation with the relicensing stakeholders after the initial study results have been completed.

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

Task 6: Persistent Habitat Analysis and Mapping (Reach 3)

The objective of the persistent habitat analysis is to evaluate the relationship between short-term hydrologic variability (i.e., peaking flows) and immobile aquatic species' habitat. Immobile aquatic species are those that are considered unable to move from one location to a more suitable location in the time frame of a typical peaking cycle (e.g., mussels, incubating eggs, early fry, etc.). A persistent habitat analysis consists of first identifying "quality" habitat areas (i.e., a model node's combined habitat suitability ≥ 0.5) at each modeled flow, and then matching various low and high flow pairs (e.g., 1,000 cfs and 5,000 cfs) to find the common areas of quality habitat. "Persistent" habitat is then calculated for various flow pairs on a node-by-node basis, where a node is marked as persistent habitat for that flow pair if the high and low flows (as well as any flows in between) are considered quality habitat. The analysis results can be mapped to visualize what areas provide consistently good habitat throughout the target flow range. The results from this task will include a low/high flow habitat matrix for each target species/life stage and a series of maps depicting persistent habitat for a variety of flow ranges covering expected operation flows.

Task 7: Study Report

A draft report will be prepared for study team review and comment, documenting methods and results. The report will quantify flow/WUA relationships for applicable species and lifestages in each study reach. WUA and supporting hydraulic data will be presented in graphic and tabular form, along with an analysis of trends in the data, and documentation of study team consultation. Appendices will also include cross-sectional survey data and reference photographs of study sites. The report will be finalized following receipt of input from the study team.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The estimated cost for the study outlined in this plan is approximately \$200,000-\$250,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight is proposing to commence this study before the FERC Study Plan Determination is issued, which is due by September 12, 2013. In developing this study plan, meetings were held with the state and federal resource agencies including NOAA, USFWS, MADFW, and MADEP to help jump-start the study planning.

However, to ensure all interested parties have input on the study plan, it will be provided to all parties on the mailing list and a meeting will be held to solicit and address issues on the plan on April 16, 2013 at the Northfield Mountain Visitor Center (99 Millers Falls Road, Northfield, MA). For those who cannot attend the meeting, FirstLight requested written comments be sent by April 5, 2013 to the following email address: firstlight@gomezandsullivan.com.

The accelerated schedule for this study is listed below.

TASK	COMPLETION DATE
Finalize flow targets, study reaches, species and lifestages	April, 2013
Finalize HSI curves to be used	May, 2013
Select study sites and cell boundaries	June, 2013
Collect hydraulic and bed profile data	July, 2013

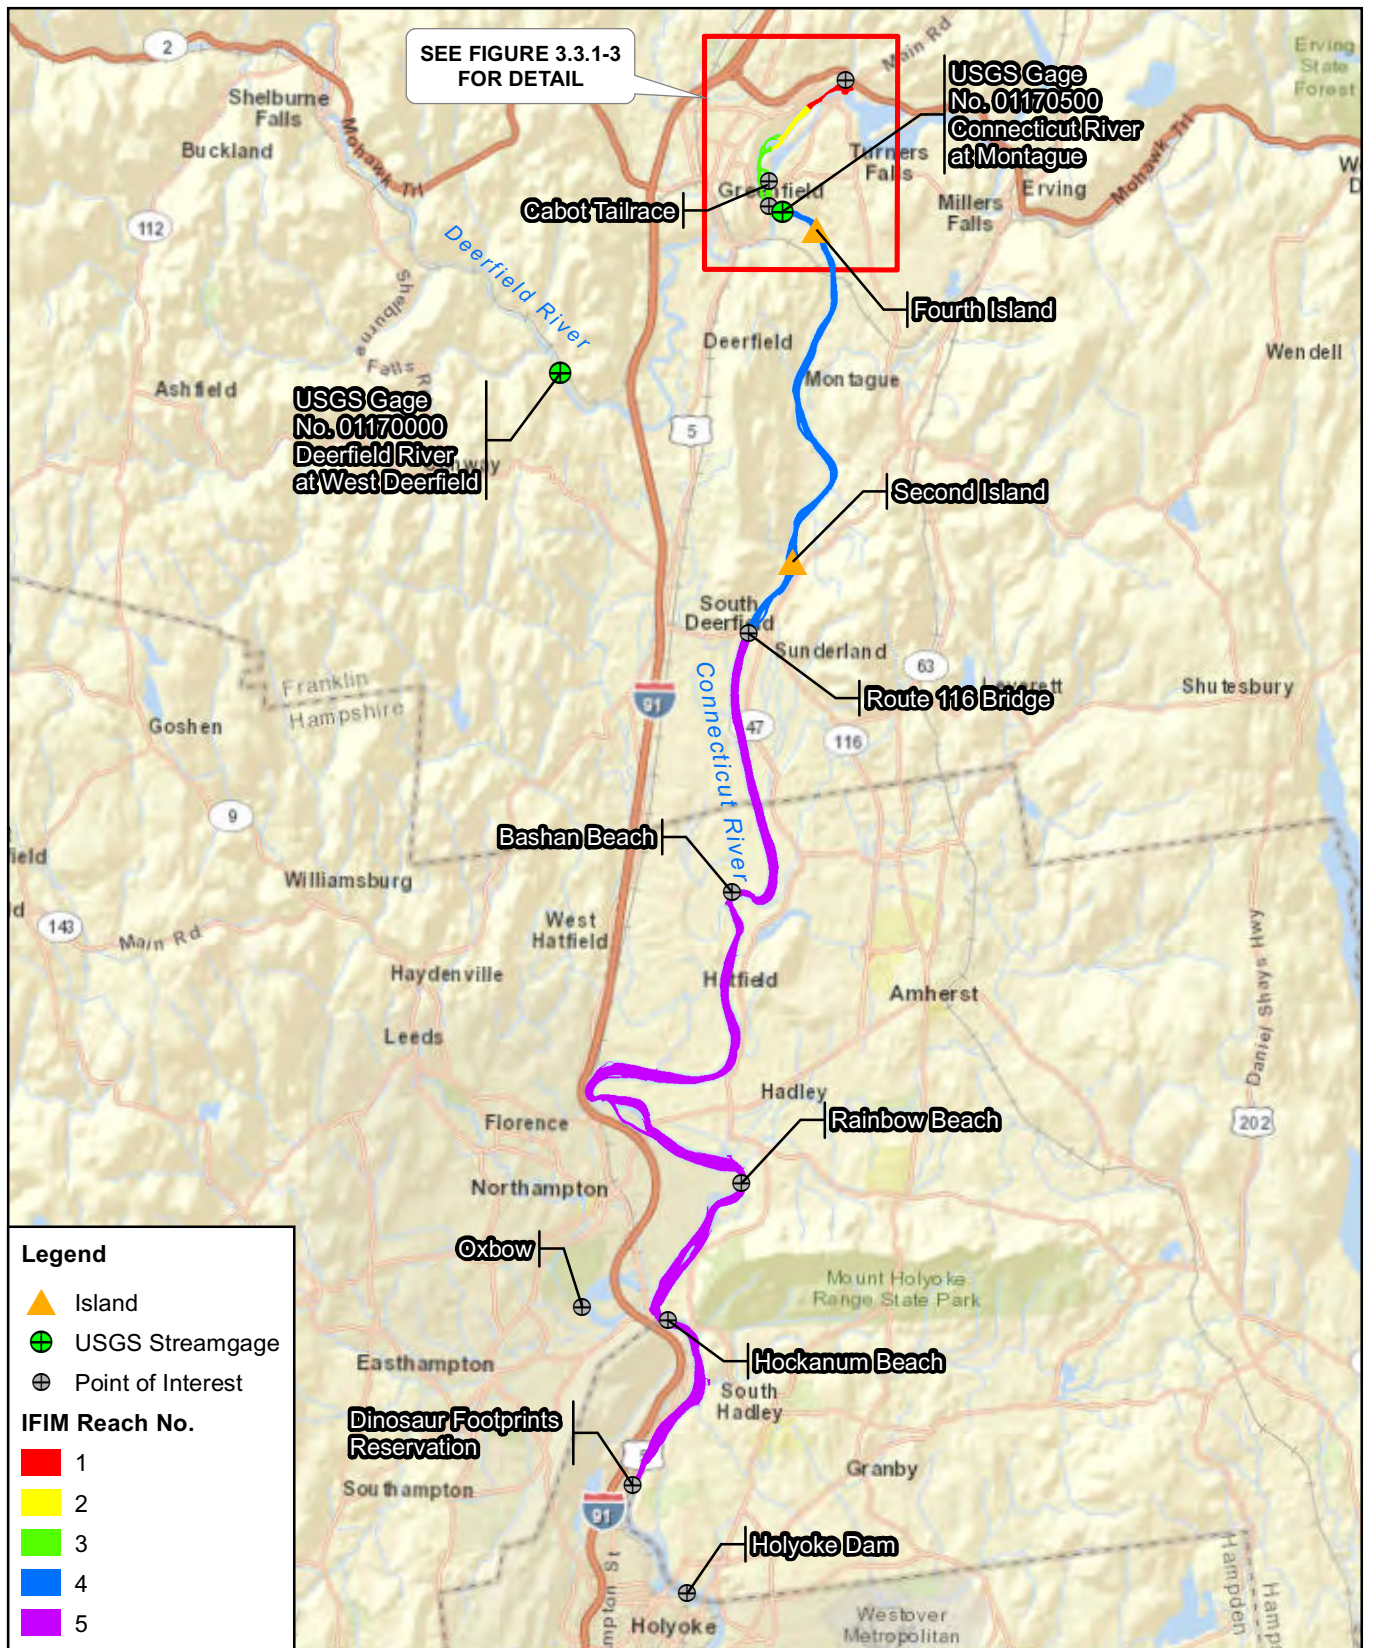

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

TASK	COMPLETION DATE
Complete modeling	September, 2013
Issue draft report	October, 2013
Issue final report	December 1, 2013

3.3.2 Evaluate Upstream and Downstream Passage of Adult American Shad**General Description of Proposed Study**

An evaluation of upstream and downstream passage of adult American shad has been requested by FERC, USFWS, NOAA, MDFW, NHDES, NHFG, VTDEC, CRWC, TU and the Town of Gill. A telemetry study with both radio and Passive Integrated Transponder (PIT) tag types will be conducted to assess behavior, approach routes, passage success, survival, and delay by adult American shad as they encounter the Turners Falls Project and Northfield Mountain Project during both upstream and downstream migrations. Additionally, video recording techniques will be used to evaluate passage efficiency more precisely at the Spillway fishway. FirstLight has spent considerable effort in the past studying adult shad passage at the Cabot and Gatehouse ladder (*see* Appendix E). As an initial phase of this study, FirstLight proposes to evaluate this information relative to the objectives of this study to determine if additional field data collection and analysis in these two specific locations is warranted.

A potential alternative to the current configuration of fishways at the project would be to minimize attraction to the Cabot ladder and operate a single fish lift facility at the dam. For this to be effective, attraction of shad to the Cabot Station discharge and associated delays would need to be overcome. The effect of different levels of dam releases that would induce fish to move past the Cabot Station into the bypass reach and up to the dam will be evaluated. In addition, it is possible that spillway flow releases coupled with a high frequency ultrasound array at the Cabot Station may dissuade shad from entering that tailrace. [Study No. 3.3.19 Evaluate the use of an Ultrasound Array to Facilitate Upstream Movement to Turners Falls Dam by Avoiding Cabot Station Tailrace](#) proposes to evaluate the use of an ultrasound array to guide fish past the Cabot Station tailrace.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to identify the effects of the Turners Falls and Northfield Mountain Projects on adult shad migration. The study objectives are to:

- Develop a detailed study plan after previously collected data are analyzed;
- Identify migration delays resulting from continued operation of the Turners Falls Project;
- Determine route selection and behavior of upstream migrating shad at the Turners Falls Project under various spill flow levels;
- Evaluate attraction, entrance efficiency and internal efficiency of the spillway ladder for shad reaching the dam spillway, under a range of spill conditions;
- Evaluate migration through the Turners Falls Impoundment;
- Identify impacts of Northfield Mountain operations on upstream and downstream adult shad migration, including delays, entrainment, behavioral changes and migration direction shifts.
- Determine downstream passage route selection, timing/delay, and survival into the power canal and spill flows at Turners Falls Dam; and
- Determine downstream passage route selection, timing/delay in the canal, Cabot Station fish bypass facility effectiveness, and survival of Cabot-bypassed adult shad that enter the Turners Falls power canal.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

In 1992, the Connecticut River Atlantic Salmon Commission (CRASC) developed a draft document titled: *A Management Plan for American Shad in the Connecticut River Basin*.

Management objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
- Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, aims to maximize the number of juvenile recruits emigrating from freshwater stock complexes via the following objectives::

- American shad must be able to locate and enter the passage facility with little effort and without stress.
- Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
- Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.
- To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

Based on the CRASC plan, USFWS seeks the accomplishment of several resource goals and objectives through the relicensing process for the Turners Falls Project and Northfield Mountain Project. Specific to American shad movement and migration, the agency's goal is to minimize current and potential negative project operation effects such as migration delays, false attraction, turbine entrainment, survival of project passage routes, and trashrack impingement that could hinder management goals and objectives.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))*Shad Migration through Turners Falls Impoundment*

Adult shad movements within the Turners Falls Impoundment were monitored during 1973-1975, primarily in the vicinity of the Northfield Mountain facility and the Vernon Dam tailrace ([Layzer, 1975; 1977](#)); these studies identified four patterns of movement throughout the impoundment and determined that fish were often located in deeper areas. The location with the most shad detections was a deep area below the Northfield Mountain tailrace ([Layzer, 1977](#)). A deep, turbulent area known as the Narrows was identified as a location where delay occurred ([Layzer, 1975](#)).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Passage through the Turners Falls Complex

Many previous studies have been conducted on shad migration and/or passage within the Turners Falls Complex; for a list of each, see Appendix E. Adult shad movements have also been studied in the Turners Falls power canal starting in the mid-1980's ([BioSonics, 1985](#); [ERC, 1987](#)); the Gatehouse fishway was identified as a difficult area of passage. More recently, researchers at the Conte Lab have expended considerable effort monitoring passage at Turners Falls Dam, with PIT, telemetry, or a combination of those methods having been employed from 1999 through 2010. PIT tagging studies, sometimes in combination with telemetry, were conducted during 2000-2003. These studies primarily evaluated shad passage performance through the Turners Fall Complex; areas of evaluation included the Cabot fishway, Spillway fishway, Gatehouse gallery and fishway, the power canal, and the river from Holyoke to Turners Falls ([Sullivan et al., 2002](#); [CAFRC, 2003](#)). Further PIT tag assessment of the Cabot fishway ([Sullivan, 2004](#)) determined that 57% of shad that enter the fishway do not ascend past the lower third of the fishway, and primary problems within the ladder were identified ([Haro & Castro-Santos, 2005](#)). In general, the numbers of fish passing through the Spillway fishway were too low for rigorous evaluation ([Haro & Castro-Santos, 2005](#)). Some of the most recent studies have evaluated adult shad passage into the Gatehouse fishway using radio telemetry following modifications intended to improve passage there ([Haro & Castro-Santos, 2009](#); [Haro & Castro-Santos, 2010](#)). Passage through the Gatehouse improved after modifications, but the studies were unable to discern the ultimate cause of improved passage because multiple modifications were made. This study also found that fish which were transported from Holyoke exhibited improved passage relative to those which ascended the Cabot fishway, possibly indicating that stress and delay through the Cabot fishway could result in reduced passage at the Gatehouse.

Whole-River Telemetry Studies

In addition, whole-river shad telemetry studies were performed in 2011 and 2012. These data should allow quantification of delay below Turners Falls, and could help guide studies requested above. Preliminary analyses of data through 2011 have been made available to FirstLight and the resource agencies. The whole-river studies have also shown that, at least in 2011, most shad that pass Turners Falls rapidly progress upstream to Vernon Dam. Similar patterns were noted in 2012 (T. Castro-Santos, personal communication). Similarly, concerns relative to the downstream passage of spent shad also remain relative to delays, with existing unpublished USGS telemetry data sets suggesting this is may be issue within the Turners Falls power canal.

The Need for Additional Information

Due to the relatively large amount of data gathered by previous studies, it is possible that some objectives of this study may already be partially satisfied, or that this study could be designed to address questions raised by results of those data; however, the data require further analysis prior to making conclusions regarding how they apply to this study or how the results may alter the design.

Project Nexus (18 CFR § 5.11(d)(4))

Project operations may affect passage route selection, entry into fishways, and create delays to upstream and downstream migration. The project's upstream and downstream passage facilities should be designed and operated to provide effective upstream and downstream fish passage.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The proposed study will build and expand on the information collected by the Conte Lab and FirstLight. Previous data will be used to identify potential locations where further or more detailed information is

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

required to evaluate shad migration through the Turners Falls and Northfield Mountain projects; after a detailed study design is developed, shad migration will be monitored using telemetry and video monitoring techniques.

Task 1: Review Existing Information

Analysis of previously collected data will be completed in 2013 to help inform the design of subsequent field studies and to determine whether some objectives have already been met with recent existing data. Substantial data have already been collected at Turners Falls Project from multiple years of passage assessments conducted for FirstLight by Conte Lab researchers, which will be useful to determine whether further study of those areas is required or if this study should focus efforts elsewhere. Data were also collected for the 2011 and 2012 full river study conducted by the Conte Lab that address migration and passage questions at the Turners Falls and Northfield Mountain Projects that have not yet been analyzed. Relevant data from the project area will be analyzed as part of this study.

Task 2: Develop Study Design

Once the analysis of existing data is completed in 2013 a detailed study design will be developed in consultation with the resource agencies and will specify sample sizes, tag configurations and receiver configurations. Existing information on captured, handled, and tagged fish performance, along with other factors such as timing of tagging and potentially transport, will be considered to ensure an adequate sample size of healthy tagged fish is available to address study objectives. An array of stationary monitoring stations (radio and PIT) will be designed to address the issues identified among the project areas, and will provide an appropriate level of resolution to fulfill the objectives of the study.

A plan and schedule for dam flow releases will be developed. Flows between 2,500 and 6,300 cfs will be evaluated as they have been identified as the range of flows needed for successful spawning for ESA-listed shortnose sturgeon which occurs at the same time as upstream shad passage.

Task 3: Evaluation of Route Selection and Delay*Radio Telemetry Tracking*

Information to address many of the objectives would rely on the tagging of upstream migrating adult shad. Fish will be captured at Holyoke Dam, tagged with radio and PIT tags, and released upstream of Holyoke Dam. Tagged fish will be tracked throughout the study area during both upstream and downstream migration with fixed arrays and via manual tracking; the use of PIT tags in addition to radio telemetry tags will provide an inexpensive safeguard in the event of radio tag loss, and would also allow for precise tracking within fishways if necessitated by Task 2. Use of radio, including PIT telemetry is a widely accepted method to assess fish migratory behavior and passage success and has been used to assess migration and passage issues at the Turners Falls Project, as well as other Connecticut River projects. However, these methods have also been shown to alter the behavior and mortality of tagged fish; consideration of these alterations will be important for determining the adequate sample size during the development of the study design in Task 2.

Additional tagged individuals may need to be released farther upstream (Turners Falls power canal, upstream of Turners Falls Dam), to ensure that enough tagged individuals encounter project dams on both upstream and downstream migrations, that these individuals are exposed to a sufficient range of turbine and operational conditions to test for project effects, and to provide adequate samples sizes in order to address the objectives.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Video Monitoring

Video monitoring will be used for specific study areas such as the Spillway fishway. Use of video monitoring of the Spillway fishway will provide additional overall data on fishway efficiency; all shad attempting to pass would be monitored versus only those shad that have been tagged. FirstLight proposes to conduct video monitoring using the Delta Vision commercial series of underwater video camera and lighting manufactured by Ocean Systems Inc. Video data will be recorded on a dedicated digital video recorder.

Task 4: Evaluation of Mortality

The telemetry study will be designed to use of motion sensor telemetry tags that will give researchers an indication of passage induced mortality. Mortality will be assessed at locations where tagged fish as part of the radio tracking study in Task 3 are subjected to entrainment or passage via spillage.

Task 5: Reporting

A report will be prepared including a summary of the results of the collected telemetry data along with statistically justifiable analyses of American shad migration and behavior throughout the study area in the Connecticut River. Collected biological information, water quality data, river conditions, project operations and flow conditions, and the condition of project facilities during the time of the study will be included in the report. Tagged-shad movements during the study will be graphically displayed. All data used to develop the report will be included in an appendix.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The analysis of existing data and data from the requested study will require a substantial effort and cost to capture, PIT tag, and radio tag a sufficient number of shad at Holyoke to release at upstream locations. We are not aware of any other study technique that would provide project specific fish behavior and migration information to adequately assess existing project operations and provide insight in possible alternative operations and measures needed to address impacts to fish migration success. Cost for the entire multi-project tagging, tracking and data analysis are expected to range from \$400,000 to \$500,000 based on past Turners Falls Project studies and the 2011 and 2012 shad telemetry studies. Video monitoring of the Spillway fishway would add a modest cost to this study.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

Existing data from prior adult shad telemetry efforts on the Connecticut River will be analyzed in the summer of 2013 and will provide the basis for a detailed study design which will include; sample sizes, tag configurations and receiver configuration. The detailed field study will be designed in consultation with the resource agencies.

Adult American shad migrate into the lower Connecticut River during late March or early April. Fish lift operation at the Holyoke Project, located downstream, typically begins on April 15, with shad reaching Cabot Station in late April or early to mid- May. As such, the telemetry based monitoring system will be deployed, calibrated and tested in late March and early April 2014, prior to the arrival of adult shad to the study area. Test fish will be collected at the Holyoke Project and released at various locations upstream. Prior work conducted in the Connecticut River has shown that early migrating shad have the strongest migratory drive, traveling the farthest upstream (T. Castro-Santos, USGS Conte Lab, personal communication). These early migrants will be targeted for use in the study to maximize the potential for test fish to reach and interact with the Turners Falls and Northfield Projects. American shad migrate up

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

river when water temperatures are generally between 12 and 20°C; spawning occurs from 14 to 23°C when river flow is generally declining from the spring peak. Spent outmigrants travel downstream shortly after spawning. The exact timing of the out-migration will be dependent on many factors, most notably water temperature. The study is anticipated to conclude by early July. If deemed necessary, a second year of field work may be conducted.

3.3.3 Evaluate Downstream Passage of Juvenile American Shad**General Description of Proposed Study**

An evaluation of downstream passage of juvenile American shad has been requested by USFWS, NOAA, MDFW, NHFG, VTDEC, CRWC, TU and the Town of Gill. A field study of juvenile American shad outmigration in the Turners Falls impoundment and the power canal and at Turners Falls Dam, Station No. 1, Cabot Station, and the Northfield Mountain Project will be conducted to assess juvenile American shad outmigration success.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to determine if project operations affect juvenile American shad outmigration success.

Study objectives:

- Assess the effects of the Projects on the timing, orientation, routes, migration rates, and survival of juvenile shad;
- Determine the proportion of juvenile shad that pass downstream through the power canal versus over the dam under varied operational conditions, including a range of spill conditions;
- Determine the rate of downstream movement within the impoundment, over the dam and through the bypass reach, or through the power canal;
- Determine survival rates for juveniles spilled over/through dam gates, under varied operation conditions, including up to full spill during the annual fall power canal outage period;
- Determine downstream passage timing, route selection, and rate of movement of juvenile shad through the power canal to Station No. 1, Cabot Station, and the Cabot Station bypass;
- Based upon Year 1 study results on route selection, determine the survival rate for juvenile shad entrained into Station No.1; and
- Determine the survival rates for juvenile shad entrained at Cabot Station.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

In 1992, the CRASC developed a draft document titled: *A Management Plan for American Shad in the Connecticut River Basin*.

Management Objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, aims to maximize the number of juvenile recruits emigrating from freshwater stock complexes.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

American shad have had access to spawning and rearing habitat upstream of Turners Dams since passage was provided via fishways in 1980. Effective downstream passage and successful spawning and juvenile production are necessary to help achieve shad management restoration goals for the Connecticut River. American shad broadcast spawn with the highest spawning activity occurring in runs and lowest activity in pools and riffle/pools ([Ross et al., 1993](#)). Field research by Ross et al. ([1993](#)) in the Delaware River further noted that a combination of physical characteristics that seems to be avoided by spawning adults is slow current and greater depth. American shad year-class strength has been shown to depend on parent stock size and environmental conditions during the larval life stages ([Crecco & Savoy, 1984](#)). Rate of movement in juvenile American shad outmigration may affect survival rates in the transition to the marine environment ([Zydlewski et al., 2003](#)). Juvenile shad outmigration in the Connecticut River begins when declining autumn temperatures reached 19°C and peaked at 16°C ([O’Leary & Kynard, 1986](#)). During the peak of the migration, juvenile shad captured by O’Leary and Kynard ([1986](#)) averaged 97 – 100 mm in total length.

Juvenile shad abundance has been shown to be negatively correlated with river flow in June ([Crecco & Savoy, 1984](#)). Juvenile shad are abundant in many river locations throughout the summer, where they provide a forage base for predatory fish. Although some fish may move downstream through the Project at other times, the peak seaward migration out of the Connecticut River occurs in September through November. O’Donnell and Letcher ([2008](#)) examined juvenile shad early life history and migration upstream and downstream of Turners Falls Dam. Their study results led to the decision by the agencies to require earlier operation of downstream fishways to protect early season juvenile shad out-migrants (1 September prior to 2010, 15 August in 2010, and since 2011, 1 August).

Much daily movement occurs in evening hours until about 2300 h but movement can occur round-the-clock. The young migrate to areas in the North Atlantic and remain at sea for four to six years before returning to their native river to spawn.

Downstream juvenile clupeid passage studies at Turners Falls were conducted in the fall of 1991 and 1992 ([Harza & RMC, 1992; 1993](#)) which included the objectives of determining the percentage of juvenile shad and herring that pass via the bypass log sluice or that were entrained in the Cabot Station turbines and related data (e.g., catch rates) were compared. It was concluded that only an estimated 54% (average bypass rate, weighted by estimated number bypassed) of the juvenile American shad approaching Cabot Station were bypassed via the log sluice; this estimate was greater during 1992, with 87% of juvenile shad passing through the log sluice after the installation of a new sampling device/bulkhead. A study during fall 1993 determined that a greater percentage of juvenile clupeids (94.4%) passed through the log sluice after the downstream passageway was equipped with artificial lighting ([RMC, 1994](#)).

Project Nexus (18 CFR § 5.11(d)(4))

Project operations may affect passage route selection, entry into bypasses, and rate of downstream migration. The project’s downstream passage facilities need to be designed and operated to provide effective downstream fish passage.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Adult American shad passed upstream of Turners Falls Dam utilize upstream spawning habitat. Juvenile American shad production occurs in these habitats upstream of Turners Falls Dam on an annual basis. Juvenile American shad require downstream passage to complete their lifecycle and promote recruitment to the basin.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The impact to juvenile shad outmigrants by project operations will be studied by a combination of approaches including hydroacoustic and radio telemetry, and may include the use of turbine balloon tags¹⁷. The study objectives will be met by a tasked approach and are anticipated to occur over two years of study, 2014 and 2015.

Task 1: Evaluation of Timing, Duration and Magnitude of Migration

The timing, duration, and magnitude of juvenile shad migration at the Turners Fall Project will be evaluated over a range of existing and operational conditions. In advance of the field study, test conditions will be defined in consultation with resource agencies. Hydroacoustics will be deployed in the forebay area at Cabot Station. The exact number and position of the hydroacoustic transducers will be determined in the field but it is anticipated that a surface transducer with a downward orientation would be deployed. Data from the hydroacoustics will provide information on the timing, frequency and magnitude of the migration. Shad migration through the downstream bypass will be sampled concurrently. Concurrent bypass sampling will be conducted over several discreet events such that a statistically robust comparison between the proportion of bypassed fish and those at Cabot Station can be calculated and thus provide an estimate of bypass efficiency.

Hydroacoustic data will be processed with Myriax Echoview or similar software. The data will be reduced by applying an intensity threshold that is representative of the target size and analyzed with an α,β -tracking algorithm, which identifies the series of echoes that were returned by an individual fish over successive pings. The tracking results will be reviewed on the echogram and exported as a database containing time, target strength, and 3-D positional information for each fish detected. Fish counts will be expanded for the non-sampled area of the intake cross-section. An expansion factor will be calculated for each individual fish as a function of its effective beam width at the range it was observed. This effective beam width depends on the acoustic beam pattern and the size of the target. Thus, for a given transducer, at any given range, a large fish can be detected over a wider portion of the intake cross-section than a smaller fish. The expansion factor compensates for this differential detection probability.

Task 2: Evaluate Route of Passage Choice and Delay

Radio telemetry methods will be used to assess routes of downstream passage and occurrences of delay, if feasible. Juvenile shad are fragile and can be difficult to reliably test using methods requiring fish handling and tagging such as telemetry. However, prior telemetry studies conducted with juvenile shad have had success, particularly when large sized (~120mm) hatchery juvenile test fish were used. Most wild out-migrating young of year (YOY) shad do not attain this large of a size prior to exiting the Project area (K. Sprankle, personal communication). As such, FirstLight proposes a phased approach to the juvenile shad telemetry study.

¹⁷ These tags are proprietary to the consultant representing TransCanada on the three hydropower facilities undergoing relicensing on the Connecticut River. It is unknown at this time if these tags will be available for use by FirstLight.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Phase 1 will be conducted in the first year of study in which FirstLight will conduct a proof of concept assessment to investigate the feasibility of tagging juvenile shad. A minimum of 500 juvenile shad will be collected from Connecticut River at the Turners Falls downstream bypass sampler and held for a minimum of 8 hrs in a 1000 gallon pump-through tank to investigate collection related latent mortality. Prior to tagging, test fish will be anesthetized in a solution of water and MS-222 at a concentration of 45.0-50.0 mg/L. According to the manufacturer, this concentration range provides moderately rapid anesthesia and allows fish to be tagged within two minutes of being placed in an anesthetic sink. At this concentration, fish can be placed in the anesthetic for up to 30 minutes without risk of mortality. Test fish will be fitted with an external *dummy* tag that simulates the different types of tags to be tested. Following tagging, test fish will be returned to a dedicated 1000 gallon pump-through tank and held for a minimum of 8 hrs and assessed as; alive, dead or moribund. A survival of greater than or equal to 80% will be deemed to be sufficiently effective for full scale tagging to proceed in Phase 2. Should tagging mortality exceed 20% and no incidental factors such as water quality issues can be identified, then the process will be re-evaluated and refined based on experience from the first tag group. A second test group will be tagged and evaluated. Should tagging mortality exceed 20% and no incidental factors can be identified, then FirstLight will consult with agencies and stakeholders to develop alternatives, if practicable.

If Phase 1 of the study described above indicates tagging is possible, Phase 2 will proceed. In Phase 2, routes of passage will be monitored via a radio telemetry monitoring array such that each route of passage (i.e. over the dam, Station No. 1, Cabot Station, and the fish bypass) is monitored. Study fish will be collected, tagged (radio) and released upstream of the NMPS. The exact number of tagged fish, radio receivers and antenna location, type and configuration will be determined in consultation with the agencies. Further, other previous or concurrent radio telemetry studies will inform the design.

Task 3: Survival

If possible, balloon tags will be used to empirically determine rates of survival for fish entrained at Station No. 1 and Cabot Station as well as those passed over or through the dam's gates, under varied operations, including spill conditions if possible, which typically occurs annually in the fall during the canal outage period.

The feasibility of tagging juvenile shad with balloon tags will be investigated in Task 2. Should the feasibility effort prove actionable, five groups of juvenile shad will be tagged; the sample size for each group will be determined in consultation with the agencies. One group will be injected at each of the four passage routes, dam spill or gates, Station No. 1, Cabot Station and the downstream fish bypass. The final group will provide a control group and will be held in a 1000 gallon pump-through tank over the duration of the evaluation to investigate handling and tagging related mortality.

Task 4: Reporting

The hydroacoustic, radiotelemetry and balloon tag data will be analyzed relative to passage route(s) timing, frequency, magnitude and survival. This information will be compiled into a report and will include the methods used, results, a discussion and conclusions.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort will adequately address the study objectives. The estimated cost for the study is expected to be between \$250,000 and \$350,000, with much of the costs associated with equipment (hydroacoustic gear, radio tags, radio receivers, and PIT readers) and related fieldwork labor.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The out-migration of juvenile American shad typically begins in September as water temperature begins to cool. However, recent work conducted by O'Donnell and Letcher (2008) in the Connecticut River suggests that the emigration starts as early as the middle of August. As such, the hydroacoustic monitoring equipment will be deployed, calibrated, and tested in the first half of August becoming operational no later than August 15th. The Phase 1 tagging feasibility evaluation will be conducted in September when the outmigration is expected to be at its peak. Targeting the peak outmigration for collection of Phase 1 test fish will minimize effort in the collection. Information collected in the concurrent hydroacoustic monitoring effort will help to pinpoint the peak migration. Phase 2 study tasks will be conducted during the out-migration season, August 15 through the end of October.

Downstream American eel study efforts (Section 3.3.5) will require hydroacoustic monitoring. These two study efforts will overlap due to the overlap in timing of outmigration of adult silver phase eel and juvenile shad. As such, these studies will be conducted concurrently, within the same study year, to take advantage of cost saving related to monitoring equipment rental, deployment, calibration, data management and analysis.

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

In accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1, the study will be completed according to the milestones below.

3.3.4 Evaluate Upstream Passage of American Eel at the Turners Falls Project**General Description of Proposed Study**

An evaluation of upstream American eel passage has been requested by USFWS, NHFG, MDFW, NHDES, VTDEC, CRWC, and TU. FirstLight proposes to complete a study to assess upstream American eel passage at the Turners Falls Project through visual observations of eel concentration areas and trapping methods. FirstLight anticipates conducting visual surveys for eel concentration areas in 2014 and using this information to inform trap placement in 2015.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to identify and assess potential locations for upstream American eel passage at the Turners Falls Project.

This study has two objectives:

- Identify concentrations of eels staging in pools or attempting to ascend wetted structures; and
- Assess whether eels can be passed in substantial numbers and whether sites are viable for permanent passage structures.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The goals of the Atlantic States Marine Fisheries Commission (ASMFC) management plan for American eel (2000) include: (1) protect and enhance American eel abundance in all watersheds where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel (letter from NOAA Fisheries, Comments on FirstLight Power Resources Notice of Intent to File License Application, February 27, 2013). Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process (letter from NOAA Fisheries, Comments on FirstLight Power Resources Notice of Intent to File License Application, February 27, 2013).

In addition, the CRASC developed a Management Plan for American eel in the Connecticut River Basin in 2005. The goal of the plan is “*to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem.*” Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin, and;
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

While eels have been known to ascend the Turners Falls fishways, their efficiency is unknown and they are typically operated only during the American shad passage season. Eels are currently able to pass the

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Turners Falls Dam complex (as evidenced by documented presence of eels upstream), but the total number of eels attempting to pass Turners Falls and the proportion successfully passing the Turners Falls Project are unknown (letter from NOAA Fisheries, Comments on FirstLight Power Resources Notice of Intent to File License Application, February 27, 2013).

The Holyoke Project has operated upstream eel passage facilities since 2004. In 2012, these facilities passed over 40,000 juvenile eels (letter from NOAA Fisheries, Comments on FirstLight Power Resources Notice of Intent to File License Application, February 27, 2013). There is eel rearing habitat in the 35-mile reach between the Holyoke and Turners Falls Dams; however, it is likely that some eels will attempt to continue upstream to access habitat above the Turners Falls Dam.

Project Nexus (18 CFR § 5.11(d)(4))

The Turners Falls Project may directly impact upstream American eel as Project structures create impediments to migration.

The investigation area includes the following features of the Turners Falls Project:

- Cabot Station discharge area.
- Station No. 1 discharge area.
- Various canal discharge areas.
- Turners Falls Dam.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The study will be performed in accordance with the following methodologies.

Task 1: Systematic Surveys

Systematic surveys of eel presence and relative abundance will be conducted six times during the 2014 eel upstream migratory season. The first survey will be initiated within one week of eels being observed downstream of the project area at the Holyoke eel pass, with subsequent surveys occurring at night after precipitation events and around new lunar cycles throughout the 2014 migration season. Each survey will consist of visual inspection in areas where eels are likely to concentrate as they attempt to climb structures wetted by spill or leakage flow in the Turners Falls Dam complex area. These locations, shown in [Figures 3.3.4-1](#) and [3.3.4-2](#), include:

- Cabot Station log sluice (downstream fish bypass).
- Cabot Station spillway (emergency water control gates).
- Cabot Fishway (dewatered state).
- USGS Conte Lab flume outfall.
- Station No. 1 outfall.
- Small turbine and process water outfalls from the Cabot Canal.
- Spillway fishway attraction water stilling basin.
- Leakage points along the downstream face of Turners Falls Dam (as site conditions allow for safety).

Recorded data will include location, observation of eels (presence, absence) and relative numbers, relative sizes, behaviors, and time/date of observation, where applicable.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Trap Collections

Areas identified in Task 1 as having eels present in sufficient numbers will be targeted as potential areas for permanent eel trap/passes and will be initially assessed using temporary/portable traps in 2015. At a minimum (regardless of survey results), temporary traps will be installed at the following locations in 2015:

- Cabot fishway attraction flow stilling basin (during dewatered fishway period),
- Station No. 1 discharge, and
- Spillway fishway attraction flow stilling basin (during watered and dewatered fishway period).

The temporary trap/passes will be designed and built for each location, and operated throughout the eel upstream migratory season, beginning within one week of eels being recorded at the Holyoke eel pass and continuing until less than 10 eels are observed across all three traps. Ramp-type traps with supplementary attraction flow will be used. Traps will operate daily (24 hours per day) and will be checked periodically to quantify the catch. Recorded data will include location, trapping interval, numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.

Eels collected from trap/pass collections will be transported to and released in the Turners Falls Impoundment.

Task 3: Data Analysis

All field data will be compiled, entered into a database, assured for quality, and archived. Tabular and graphic summaries of eel abundance by location will be developed.

Task 4: Reporting

A report will be prepared describing monitoring methods and results. The report will be submitted as part of the Initial Study Report as per the ILP process schedule.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The level of effort for Task 1 of the American eel study (Systematic Surveys) will include at least six (6) evening surveying events. Cost of this effort including equipment is estimated to be \$12,000 to \$18,000. The 2015 effort to place temporary ramps at identified concentration areas and checking collection boxes on a routine basis (Task 2) will cost between \$25,000 and \$35,000. The total cost for this study ranges from \$37,000 to \$53,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

Systematic surveys and trapping to evaluate eel presence and abundance will be conducted six times throughout the eel upstream migratory season (approximately May 1 to October 15, dependent on river temperatures and observations at the downstream eel pass) in 2014. Results will inform locations for installing temporary trap/passes during the same period during 2015.

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

3.3.5 Evaluate Downstream Passage of American Eel**General Description of Proposed Studies**

The USFWS, NHFG, MDFW, NOAA, VTDEC, TU, and CRWC have requested two specific studies regarding downstream passage of adult American eel. The first study request was for a timing evaluation of downstream migratory movements of American eel on the mainstem Connecticut River. The second study request was for an assessment of downstream American eel passage at the Turners Falls Project and Northfield Mountain Project. The study proposed herein will be conducted over two years and will use radiotelemetry and hydroacoustic methods to investigate the timing of silver phase eel outmigration in the Connecticut River and routes of passage through the Turners Falls Project.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goals of these studies are to:

1. Better understand migration timing of adult, silver-phase American eel as it relates to environmental factors and operations of the Turners Falls Project and Northfield Mountain Project.
2. Determine the impact of the Turners Falls Project and Northfield Mountain Project on the outmigration of silver eel in the Connecticut River.

Specific objectives of these studies are to:

1. Quantify and characterize the general migratory timing and presence of adult, silver-phase American eel migrating past the Turners Falls Project and Northfield Mountain Project relative to environmental factors and operations.
2. Quantify movement rates and proportion of eel passing via various passage routes at the Turners Falls Project and Northfield Mountain Project. For the Northfield Mountain Project, the study will evaluate the proportion of eel entrained into the intake. For the Turners Falls Project, the study will evaluate the proportion of eel passing via the available routes of passage at the complex.
3. Evaluate survival of adult silver eel passed at the available routes of passage at the Turners Falls complex.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

Based on management plans developed by the ASMFC and the CRASC, the resource management goals identified by the commenting agencies are to:

- Ensure PME measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Specific goals with respect to downstream passage of American eel are to:

- Minimize current and potential negative project operation effects that could hinder management goals and objectives.
- Minimize project-related sources of downstream passage injury, stress, and mortality in order to maximize the number of silver eel migrating to the spawning grounds.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

According to the commenting agencies, data on the timing of downstream migratory movements and rates of American eel in the mainstem Connecticut River are sparse and relatively incomplete. Preliminary data on the presence of “eel-sized” acoustic targets have been collected ([Haro et al., 1999](#)) within the Cabot Station forebay that were somewhat confirmed by video monitoring at the Cabot Station downstream fish bypass; however, these were short-term studies, with acoustic monitoring only performed from 17 September to 5 October and video monitoring only conducted between 18 September to 22 October. Some daily monitoring of the downstream fish bypass at the Holyoke Dam (canal louver array) was performed in 2004 and 2005 ([Kleinschmidt Associates, 2005](#); [2006](#); [Normandeau Associates, 2007](#)); these studies also were of relatively short duration (spanning from October 5 to November 10 in 2004 and September 9 to November 11 in 2005) and the sampler was operated at night. To date, no other directed studies of eel migratory movements have been conducted at any location on the Connecticut River mainstem (letter from MDFW, Comments on FirstLight Power Resources Notice of Intent to File License Application, February 28, 2013).

As discussed in the PAD, 2-D and 3-D telemetry studies were conducted at Cabot Station in 1996, 1997, 2002 and 2003. Results of those studies indicate that a significant proportion of eel entering the Cabot forebay become entrained (90% in 2002, 100% in 2003; [Brown, 2005](#); [Brown et al., 2009](#)). The PAD notes that the study done in 2003 determined that 15 of the 29 test eel were detected at the Hadley Falls Station. However, that study was not designed to assess turbine mortality. The approach velocity at the Cabot Station racks is approximately 2.0 feet per second at maximum hydraulic capacity. At Station No. 1, the racks have 2.6-inch clear spacing and an approach velocity of 1.2 feet per second. The intake at the Northfield Mountain Project has 48-foot-deep trash racks with six-inch clear spacing over the intake and an approach velocity of 3.5 feet per second at full pumping capacity (15,000 cfs).

To date, no directed studies of eel mortality at Cabot Station or eel entrainment or mortality at either Station No. 1 or the Northfield Mountain facility have been conducted.

Existing research and literature on the American eel relevant to these proceedings includes the following:

Project Nexus (18 CFR § 5.11(d)(4))

Project operations may directly or indirectly affect eel outmigration in the fall through entrainment, rate of movement, injury, or mortality. Baseline information related to the timing and passage of outmigrating eel will allow stakeholders to assess project-related effects on eel migratory success and survival.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The sample size of test fish will be determined in consultation with the resource agencies with the intent of reaching an agreement on adequate sample size such that FirstLight and the resource agencies will have confidence in the test results.

Task 1: Evaluate Timing of Downstream Migratory Movements

Task 1 will be conducted in the first year of study (2014) and in tandem with the juvenile shad study (see Section 3.3.3). The timing of eel migration as it relates to environmental factors and operations of the Turners Falls Project and Northfield Mountain Project will be assessed through the use of hydroacoustic techniques. Hydroacoustic equipment will be installed within the Cabot Station forebay to provide information on the timing, magnitude, and duration of adult eel passage through this area. Because eels tend to concentrate in areas of dominant flow¹⁸, the hydroacoustic zone to be monitored will target a portion of the dominant flow through the project (i.e., forebay intake area). Hydroacoustic monitoring will encompass the entire potential migratory season, beginning in mid-August and ending in mid-November. Data will be recorded for later processing and archiving. Concurrent sampling will also occur at the Cabot sampler on at least 10 evenings to ground truth the hydroacoustic data and compare the percent of eels passing via the Cabot sampler and Cabot Station.

In addition, project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, air temperature, and precipitation amounts) will be monitored following standard methodology throughout the duration of the studies.

¹⁸ [Brown et al., 2009](#); [EPRI 2001](#).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

One year of hydroacoustic sampling is being proposed. If the 2014 season is a typical flow/weather season, then that would conclude this effort. If the 2014 season is not typical, then a second season would be considered based upon discussions with the resource agencies.

Task 2: Assessment of Downstream Passage of American Eel

Task 2 will be conducted in the second year of study (2015). FirstLight will assess downstream passage and entrainment survival of adult American eel through use of radio-telemetry techniques. FirstLight will use the findings from the 2014 hydroacoustic study to inform the 2015 studies.

FirstLight will use radio telemetry techniques to monitor adult downstream eel passage at the Turners Falls Project and Northfield Mountain Project. For the Northfield Mountain Project, the study will evaluate the proportion of tagged eel entrained into the intake. For the Turners Falls Project, the study will evaluate the proportion of eel passing via spillways, gates, turbines, and the existing fish bypass at Cabot Station and/or Station No. 1. The route of passage study will be designed with the use of motion sensor telemetry tags that will give researchers an indication of passage-induced mortality.¹⁹ This phase of the study will involve systematic releases of radio-tagged silver phase eels at strategic points above areas of interest to assess general routes of passage (i.e., via spill, fish passageways, or turbines).

Emigrating silver phase eels will be collected at the Cabot bypass sampler or the Holyoke Canal bypass sampler. Eels selected for tagging will meet morphometric (e.g., eye diameter relative to body size - Pankhurst Index of approximately 6.5 or greater) criteria to ensure they are migrant silver phased eels. Collections will be made within the migratory season (late August to mid-October), and eels will be tagged and released within seven days of collection.²⁰ In addition, project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, water temperature, air temperature, and precipitation amounts) will be recorded throughout the duration of the studies.

Task 2a: Northfield Mountain Route Selection Study (i.e., Entrainment to Northfield Mountain intakes)

Groups of test fish will be tagged and released approximately 5 km upstream of the Northfield Mountain Project to increase the likelihood that they will move downstream and interact with Project facilities. Approximately three radio telemetry antenna arrays will be strategically placed within or near the intake area to determine times eels are present within the river reach in the immediate vicinity of the Northfield Mountain Project intakes, within the intakes themselves, and whether they are entrained into the upper reservoir.

Task 2b: Turners Falls Dam Route Selection Study

Groups of test fish will be tagged and released approximately 3 km upstream of the Turners Falls Dam. Groups of eels will be released during spill and non-spill periods and during periods of low, moderate,

¹⁹For example, if an eel goes into an immobile state for a period of 36 hours, the tag's code will be programmed to switch signal transmission patterns (e.g., to a different code or different burst rate).

²⁰ The timing of collection, tagging, and release will be entirely dependent on migratory patterns and weather/river conditions. All tagged eel will be released at night during inclement weather or with inclement weather pending to increase the likelihood that eel will move soon after release. Though FirstLight will target a seven day hold period, riverine conditions may not be adequate for release, and therefore hold times may last longer than seven days. Migratory movements of silver eel have been noted after hold periods longer than seven days during several recent radio-telemetry studies at hydroelectric facilities in the northeast [(see FERC projects P-2364 (Abenaki), P-2365 (Anson), P-2325 (Weston)].

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

and high generation conditions if possible. Telemetry receivers and antennas will be positioned to monitor the following potential routes of passage:

- Within the power canal.
- Near the bascule gate(s).
- Near the tainter gate(s), if appropriate to the typical depth of the openings.
- Within the bypass river channel.
- Turners Falls spillway fishway attraction water intake (if operational).
- Station No. 1 turbines.
- Cabot Station log sluice (downstream fish bypass).
- Cabot Station spillway (emergency water control gates).
- Cabot Station turbines.
- Route 116 Bridge.

After the first group of eels is released and tracked through the Project, FirstLight will determine the areas of egress and consult with the agencies to determine if additional releases are warranted.

Task 2c: Mobile Tracking

Modifications to the location and number of receivers/antenna may occur during study set-up due to conditions encountered in the field; however, the intent is to monitor the above-named potential routes of passage. Aerial yagi and/or droppers will be used. Eels released above the Northfield Mountain intake that enter the lower end of the Turners Falls Impoundment (i.e., not entrained at Northfield Mountain) will be used to supplement the release groups. Mobile tracking (i.e., via boat, vehicle, or by foot) in river reaches between release sites and several km downstream of Cabot Station will be performed at regular intervals during and after releases to confirm routes and fates of passed fish, or fish lost to follow-up. Movement rates (time between release and passage) of eels passing the projects by various routes will also be quantified.

Tags will be programmed to transmit on several different frequencies to avoid interference or tag signal collision. Tag pulse will likely be programmed at 2 second intervals with a battery life of approximately 50 days. As possible, DSP-type receivers will be utilized to avoid the need to switch between frequencies, thereby reducing the potential for missed detections. Prior to release of tagged eel, FirstLight will perform testing and range verification during set-up to minimize overlap of detection field while maximizing detection range. As needed, beacon transmitters will be employed at strategic locations to provide a repeated data stamp during the study to verify receiver functionality.

Task 3: Data Management and Analysis

Data from hydroacoustic timing studies (Task 1) will be collected in the field and transferred to an electronic format. All data entry will be assured for quality per existing data QC protocols. These data will be processed with Myriax Echoview or similar software. The data will be reduced by applying an intensity threshold that is representative of the target size and analyzed with an α,β -tracking algorithm, which identifies the series of echoes that were returned by an individual fish over successive pings. The tracking results will be reviewed on the echogram and exported as a database containing time, target strength, and 3-D positional information for each fish detected. Eel counts will be expanded for the non-sampled area of the intake cross-section. An expansion factor will be calculated for each individual eel as a function of its effective beam width at the range it was observed. This effective beam width depends on

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

the acoustic beam pattern and the size of the target. The expansion factor compensates for this differential detection probability.

Data from the adult eel telemetry study (Task 2) will be collected regularly from the field during the study periods (i.e., at 2 to 3 day intervals). Data will be archived and entered into an MS Access or MS Excel database for sorting and post-processing. All data entry will be assured for quality per existing data QC protocols. To the extent possible, routes of passage will be determined. Route determinations will be based on logical chronological detection of individual eel movements through the telemetry monitoring arrays or in some instances, route of passage determinations will be inferred logically in the event that eel are not detected at all stations in an upstream to downstream direction. Additionally, route-specific survival will be determined by the sensor tag and is based upon an eel resuming typical migratory behavior downstream.

Task 4: Reporting

The report will be submitted as part of the Initial Study Report as per the ILP process schedule.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Projects on downstream passage and timing of adult eel in the investigation area. The estimated cost for this study is approximately between \$250,000 and \$350,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

Task 1 will be conducted in the first year of study (2014) and in tandem with the juvenile shad study (see [Section 3.3.3](#)). Task 2 will be conducted in the second year of study (2015).

In accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1, the study will be completed according to the milestones below.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.3.6 *Impact of Project Operations on Shad Spawning, Spawning Habitat and Egg Deposition in the Area of the Northfield Mountain and Turners Falls Projects***General Description of Proposed Study**

The following stakeholders requested studies to investigate the impact of project operations on shad spawning, spawning habitat and egg deposition within the project boundary: USFWS, MADFW, NHFGD, NHDES, CTRWC, NOAA, the Town of Gill, TU, and VTDEC. Section 4.4.5 of the PAD identifies several migratory species of fish that seasonally occur in the aquatic habitat within the Project boundary. One such species, the American shad (shad), seasonally migrate into the Connecticut River to spawn, reaching Project waters in late April or early to mid- May. Much of the aquatic habitat downstream of Cabot Station is suitable for shad spawning, and the reach of the Connecticut River including the Deerfield River confluence is thought to be particularly productive spawning habitat. This reach is in relatively close proximity to Cabot Station and as such is susceptible to water level fluctuations due to station operational changes. The study described herein, will investigate the effects of operational changes and subsequent flow/water level fluctuations on spawning shad in the Connecticut River.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

Determine if project operations (under the permitted and proposed operational ranges) affect shad spawning site use and availability, spawning habitat quantity and quality, and spawning activity in the river reaches downstream from Cabot Station and in the project bypass reach of Turners Falls Dam, in the Turners Falls Dam Impoundment and in relation to Northfield Mountain Pump Storage operations.

Specifically, the shad spawning study will:

- Determine areas utilized by shad for spawning by conducting night-time visual observation of spawning activity,
- Identify and define those areas geospatially, and obtain data on physical habitat conditions effected by project operations (e.g., water depth, velocity, discharge, substrate, exposure and inundation of habitats);
- Determine project operation effects on observed spawning activity, under a range of permitted or proposed project operation conditions;
- Quantify effects (e.g., water velocity, depths, inundation, exposure of habitats) of project operation on identified spawning areas for a range of conditions, over the complete period of spawning activity;
- Quantify spawning activity as measured by night-time spawning/splash surveys in areas of spawning activity, and downstream of these areas, to further determine project operation effects (location extent of exposure from changing water levels and flows and on associated habitats from project operations).

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The CRASC was established by Congress in 1983 (and reauthorized in 2002 for another 20 years) through the Connecticut River Atlantic Salmon Compact (Public Law 98-138).

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River Basin* in 1992. Management Objectives in the plan include the following:

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, aims to maximize the number of juvenile recruits emigrating from freshwater stock complexes through the following objectives:

- To mitigate hydrological changes from dams, consider operational changes such as turbine venting, aerating reservoirs upstream of hydroelectric plants, aerating flows downstream, and adjusting in-stream flows.
- Natural river discharge should be taken into account when instream flow alterations are being made to a river (flow regulation) because river flow plays an important role in the migration of diadromous fish.
- Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account instream flow needs for American shad migration, spawning, and nursery use, and minimize deviation from natural flow regimes.
- When considering options for restoring alosine habitat, include study of impacts and possible alteration of dam-related operations to enhance river habitat.

The resource agencies' goals related to aquatic natural resources include:

- Protect, enhance, or restore, diverse high quality habitat necessary to sustain healthy aquatic and riparian plant and animal communities.
- Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize the potential negative effects of project operation on water quality and aquatic habitat, and mitigate for loss or degradation.
- Conserve, enhance, and restore natural communities, habitats, and species and the ecological processes that sustain them.
- Provide a diversity of fish- and wildlife-based activities and opportunities that allow the safe and ethical viewing, regulated harvesting, and utilization of fish, plant and wildlife resources consistent with the North American model of fish and wildlife conservation.
- Ensure that PME measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Turners Falls Project.

The resource agencies' goal specific to American shad is:

- Minimize current and potential negative project operation effects on American shad spawning and recruitment.

The agency requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and PME measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), Silvio O. Conte National Fish and Wildlife Refuge Act (P.L. 102-212; H.R.794), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Atlantic

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

States Marine Fisheries Compact (P.L. 539, 77th Congress, as amended by P.L. 721, 81st Congress), and the Atlantic Coastal Fisheries Cooperative Management Act (16 U.S.C. 5107).

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream from Holyoke Dam. A number of improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad population, and numbers of shad passing Turners Falls Dam have not met CRASC management plan objectives.

In preparation of the PAD, fisheries data were compiled on the shad resources in the Connecticut River and can be found in section 4.4.5 of the PAD. American shad seasonally migrate into the Connecticut River in the spring, late March or April, to spawn; typically reaching Project waters by late April to mid-May when river flow is generally declining from the spring peak. Shad passage has been monitored at the Holyoke Dam (Figure 4.4.5-1 of the PAD) and these counts provide a comprehensive record of the number of shad that have access to the Project waters. Seasonal shad passage at the Holyoke Dam peaked at 721,764 in 1992. Population number and passage numbers past Holyoke have declined from their peak, with average Holyoke passage numbers over the last 10 years of 211,850. However, shad numbers have been on the rise since 2005 with over 490,000 shad passing Holyoke Dam in 2012.

American shad typically spawn in water ranging from 3 to 18 ft in depth, in run or glide habitat ([FirstLight, 2012](#)). However, depth is not considered a critical habitat parameter for American shad ([Greene et al., 2009](#)). Shad typically spawn at night, with males reaching spawning areas prior to females ([Greene et al., 2009](#)). Daytime spawning has been documented on overcast days or in turbid water when light intensity is somewhat diminished ([Greene et al., 2009](#)). Females are broadcast spawners, preferring to release their eggs over coarse substrates including cobble, gravel and sand ([Greene et al., 2009](#) and [FirstLight, 2012](#)). American shad are highly fecund and spawn repeatedly as they move up river ([Greene et al., 2009](#)). They exhibit asynchronous ovarian development and batch spawning with multiple females releasing their eggs at the surface where they will be fertilized by one or more males. The act of spawning can be vigorous with individual breaking the surface and is conspicuous to those that are in the right place at the right time to observe.

Most (~77%) of the 30 mile reach below Cabot Station consists of *run* mesohabitat type with coarse substrates; presence of glide habitat areas are negligible ([FirstLight, 2012a](#)). Though habitat suitable for shad spawning is abundant in the 30 mile reach downstream of Cabot Station, the area of the Connecticut River, in the vicinity of the Deerfield River confluence, is thought to be particularly productive. Layzer ([1974](#)) identified 6 spawning sites from an area below the mouth of the Deerfield River (river mile 191.9) to river mile 161.7, below the Mill River confluence in Hatfield, MA. The upstream extent of this range is in close proximity (~ 0.7 miles) to Cabot Station and therefore may be susceptible to flow changes that result from Station operation.

In 2012, FirstLight conducted studies in the late spring and summer to examine habitat conditions downstream of the Turners Falls Dam. The study documented that in low flow conditions Cabot Station project operations produced fluctuations in water level elevations that can range over 4 feet in magnitude (daily operation) at the USGS Montague Gage Station, to lower values of 2 to 3 feet at the Route 116 Bridge, Sunderland, MA (PAD).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Project Nexus (18 CFR § 5.11(d)(4))

For the purposes of this study plan the Study Area includes the Connecticut River in reaches downstream from Cabot Station to the upper extent of the Holyoke impoundment and in the project bypass reach of Turners Falls Dam, in the Turners Falls Dam impoundment and in relation to Northfield Mountain Project operations.

American shad are known to spawn at five locations downstream from the Turners Falls Project from an area below the mouth of the Deerfield River (river mile 191.9) and ten other locations downstream to river mile 161.7 below the Mill River in Hatfield ([Layzer, 1974](#), [Kuzmeskus, 1977](#)).

Shad spawning is likely influenced by river flow. Flow fluctuations may impact shad spawning activity by altering current velocities and water depth at the spawning sites. Effects on spawning behavior could include suspension of spawning activity, poor fertilization, flushing of eggs into unsuitable habitat due to higher peaking discharges, eggs dropping out into unsuitable substrate and being covered by sediment deposition and/or eggs becoming stranded on dewatered shoal areas as peak flows subside.

While several shad spawning and egg deposition studies were conducted in the 1970s, that research was aimed at assessing the potential impact of developing a nuclear power station in the Montague Plains section of the Connecticut River. There are no known studies that have been conducted that were specifically designed to determine if a relationship between spawning behavior, habitat use, and egg deposition and project operations effects of the Turners Falls Project and Northfield Mountain Project. Continued Project operation and maintenance activities could, through the manipulation of flow, affect American shad that utilize the project area for spawning. The Agencies are concerned that peaking operations may be altering spawning behavior and contributing to the failure of the Connecticut River shad population to meet management targets. This study will provide information regarding the availability of spawning habitat use and verify the presence or absence of spawning shad within the Study Area as well as spawning behavioral during operational (flow) changes at Cabot Station.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

FirstLight will investigate shad spawning within the study area to determine how operations at Cabot Station may affect spawning behavior. The investigation will include a review of existing information relative to shad spawning in the Connecticut River and a survey of the study area to identify the presence of spawning shad and investigate how flow manipulations, as a result of Project operation, affects spawning behavior.

The field studies will examine known spawning areas downstream of the Turners Falls Project, to determine operation effects on shad spawning behavior, activity, and success. Further, areas utilized for spawning by American shad will be identified in the reach of the river upstream of Turners Falls Dam extending to the Northfield Mountain Project.

Task 1: Development of a Detailed Study Plan

Existing information will be reviewed to provide further insight on shad spawning behavior, habitat preferences and factors that may affect the exact location and timing of spawning in the study area such as, diel effects, water temperature and depth, flow/velocity, and turbidity. Further, counts of shad passed at the Holyoke Dam and Turners Falls will be tracked to pinpoint the most effective timing of field surveys. Concurrent adult shad telemetry studies may also provide insight as to the location of spawning shad.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

As a first step, historic data pertaining to Cabot Station discharge and flow data will be collected to provide the basis for determining typical flow regimes during the study period. This information will be provided by FirstLight and obtained from the USGS gage located on the Connecticut River in the city of Montague (USGS 01170500) and the Deerfield River (USGS 01170000) near the town of West Deerfield, Massachusetts. It is important to show the magnitude of flow and corresponding water level fluctuation in the Connecticut River below Cabot Station when flows exceed the hydraulic capacity of the Turners Falls Project. Similarly, it will be important to show the same, when flows are within the hydraulic capacity of the Turners Falls Project.

FirstLight is developing a hydraulic model of the Connecticut River from the Turners Falls Dam to the Holyoke Dam- see [Study No. 3.2.2](#) *Hydraulic Studies of Turners Falls Impoundment, Bypass Reach, and below Cabot Station*. The hydraulic model developed for the reach between Turners Falls Dam and Holyoke Dam will be used to further inform this study. More specifically, the hydraulic model will simulate water elevations in this reach under the historic flow ranges during the spawning season. Flow data will be obtained from the Montague USGS gage. The model will be run in an unsteady mode to simulate the peaking operations of the Turners Falls Project during the spawning season. The intent of the modeling is to understand the relationship between the magnitudes of water level fluctuations due to peaking operations within the context of flows normally present during the spawning season. The hydraulic model and previous water level data collected at Route 116 Bridge and at Rainbow Beach may also place bounds on the geographic extent of the study. For example, peaking operations may have a greater impact on the magnitude of water level fluctuations closer to Cabot Station than further downstream. Based on the water level monitoring conducted at the USGS gage in Montague, Route 116 Bridge and at Rainbow Beach, the magnitude of water level fluctuation decreases and attenuates further downstream.

Task 2: Examination of Known Spawning Areas Downstream of Turners Falls Dam

Field surveys will be conducted in two phases at night from shore or by boat during periods of anticipated spawning and will be based on information collected in Task 1; Phase 1 will identify spawning locations where shad are actively spawning, and project effects will be evaluated in Phase 2. In the study area, spawning typically occurs between early May to mid-June. As such, field surveys of spawning shad will occur during this period or after a minimum of 5,000 shad have passed the Holyoke Project, located downstream. Initial surveys will concentrate on the lower study reach and progress upstream with the movement of the shad. The level of effort will be dependent on the density of spawning shad within the study area, with initial surveys to be conducted twice weekly to identify peak spawning activity.

During the peak spawning period, survey efforts will be increase to three times per week. Surveys conducted below Cabot Station will concentrate on the five known spawning locations downstream of the Deerfield River confluence (river mile 191.9) and ten other locations downstream to river mile 161.7 below the Mill River in Hatfield ([Layzer, 1974](#), [Kuzmeskus, 1977](#)).

Phase 1 of the surveys will employ methods described by Ross (1993) with the exception of egg collection and identification. Ross et al. (1993) collected eggs to further verify that the observed spawning activities were being conducted by shad rather than white sucker. This verification can be accomplished by observing adult shad during the act of spawning and thus egg collection is unnecessary to achieve the goals of this study. Adult spawning shad will be observed and quantified by counting spawning splashes over 5-min intervals between sunset and 01:00 hours. Spot lights will be used to verify that such splashes were made by spawning American shad. The species and number of fish observed and their behavior will be recorded. We assume that, though every splash may not represent actual spawning and every spawning may not be accompanied by a splash, the level of surface activity is strongly correlated with actual spawning ([Ross et al., 1993](#)). Other parameters to be measured during observed spawning events include;

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

spawn timing and location (GPS); water temperature, dissolved oxygen (DO), pH, conductivity, turbidity, depth and surface velocity; and predominant substrate type. All data will be recorded on a dedicated data sheet. The data sheet will include aerial reference images and/or maps of the study area to document the relative position of observed spawning shad and provide the information necessary to estimate the total area used for spawning as well as an index of spawning activity. The data collected in the field will be correlated to Cabot Station discharge and river flow as a function of time.

In Phase 2, the impacts of flow fluctuation on spawning shad will be investigated during the peak spawning period at spawning locations identified in Phase 1 as being affected to the greatest degree by water level fluctuations. These areas will be targeted for observations during periods of discharge fluctuation at Cabot Station. Prior to flow manipulation, data will be collected to provide a quantitative baseline of shad spawning rate. FirstLight will then manipulate discharge at Cabot Station to investigate impacts to spawning. Shad spawning rate will be investigated over a range of expected seasonal flow fluctuations based on historic discharge data at Cabot Station. Several discharge manipulations may be investigated but will begin with the most extreme fluctuations scenarios. Baseline spawning rate and behavior will be compared to those observed during periods of flow manipulation to investigate potential impacts to spawning.

Task 3: Identification of Spawning Areas Upstream of Turners Falls Dam

Less is known about spawning locations upstream of the Turners Falls Dam and the study described herein should provide insight on spawning locations upstream within the study area. As such, upstream surveys will target areas of suitable habitat for spawning, including those containing flowing waters over coarse substrates. The methodology for these surveys will focus on identifying spawning areas via splash surveys consistent with Phase 1 of Task 1.

Task 4: Examination of Identified Spawning Areas Upstream of Turners Falls Dam

If results from Task 2 indicate that project operations alter spawning rates and/or behaviors of American shad downstream of Turners Falls Dam, further investigation of areas identified upstream will be performed. Because the effects of project operations are different in the Turners Falls Impoundment relative to areas below the dam, different alternative scenarios will need to be developed and evaluated for further study. Regardless, the methodology will be consistent with Phase 2 of Task 1.

Task 5: Data Analysis and Reporting

Information collected during this study will be compiled and presented in a report, which will include a map of the study area depicting the locations of observed spawning shad; materials and methods; results; a discussion of observed spawning behaviors; and, if applicable, impacts due to operational changes.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort will adequately assess the potential effects of continued Projects operations on spawning shad and their habitat within the study area. One year of the study is anticipated to cost between \$50,000 and \$60,000. Should a second year of study be required, year two cost is anticipated to be between \$30,000 and \$40,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight will conduct this study during the 2014 spawning season, April to mid-May. The exact timing of the field survey will depend on a variety of seasonal and site specific factors but water temperature is

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

the primary factor that triggers spawning. Other factors include photoperiod, water flow and velocity, and turbidity. The timing of the survey will be further refined using information obtained from shad passage data collected downstream at the Holyoke Project fish lift and Turners Falls Project fish ladders. Further, information collected during concurrent shad migration investigations may also provide insight to the locations and timing of spawning.

3.3.7 Fish Entrainment and Turbine Passage Mortality Study**General Description of Proposed Study**

The following stakeholders requested a field study to assess fish entrainment from the Connecticut River at the Northfield Mountain Project: USFWS, NMFS, NHFG, MDFW, CRWS, TU, and Town of Gill, MA. The requested objective is to quantify the number of resident and migratory fishes entrained on an annual basis as a means to evaluate potential impacts to riverine fish populations in the Turners Falls Impoundment and transient diadromous fish populations passing through the study area. The FERC has requested a literature-based assessment of fish impingement, entrainment and survival at the Northfield Mountain and Turners Falls Projects.

Entrainment field studies of the type requested by the agencies, by themselves, provide only an estimate of annual turbine fish passage and survival, but are not sufficient to determine population-level impacts on riverine resident fish populations (FERC, 1995). In recent years, desktop entrainment analyses have been found to be adequate by the FERC for characterizing annual fish entrainment loss at hydroelectric projects. Therefore, FirstLight proposes to conduct a *desktop* fish entrainment and turbine mortality assessment of the Northfield Mountain Project. For the purposes of this desktop entrainment mortality assessment, the study area includes the Turners Falls Impoundment and the Northfield Mountain Project.

The proposed study described herein will assess the potential entrainment and turbine mortality risk of both resident and diadromous fish species within the study area. This assessment will be supplemented by radio telemetry studies of American shad and American eel proposed under other study plans (see Study Nos. [3.3.2](#), [3.3.5](#), and [3.3.6](#)), which will provide information necessary to evaluate the impacts of entrainment and turbine mortality as a result of continued Project operation.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to assess fish impingement, turbine entrainment, and turbine passage survival at the two Projects.

The specific objectives of this proposed study include:

- Estimate the potential impacts of entrainment, impingement, and turbine mortality on fish at the Northfield Mountain Project and Turners Falls Project by developing a qualitative scale of entrainment risk for resident and migratory fish species.
- Conduct a quantitative assessment of the potential impact of entrainment and turbine mortality of American shad and American eel.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The Connecticut River is home to riverine species of fish and also serves as a migratory corridor and spawning and rearing habitat for diadromous species such as Atlantic salmon and American shad. In 1967, Federal (USFWS and NMFS) and state (VT, NH, MA, CT) agencies formed a cooperative program called the Connecticut River Anadromous Fish Restoration Program (Restoration Program). The goal of the Restoration Program is to restore anadromous fish to the Connecticut River. In 1983, Federal legislation passed and gave jurisdiction over the Restoration Program to the CRASC, which also continues to work toward American shad restoration in the Connecticut River under the jurisdiction of the Restoration Plan. Further, investigating the potential impacts of continued Project operation on fisheries resources in the study area will provide the necessary baseline information to evaluate the need for mitigation measures.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

In preparation of the PAD, existing information was compiled regarding the physical characteristics of the Northfield Mountain Project and Turners Falls Project to be evaluated. Factors that affect the potential for entrainment at a hydroelectric project include the size and depth of the intakes, the hydraulic capacity and configuration of the turbines, the velocity of water as it enters the intake relative to fish swim speeds, the location of the intake relative to fish habitat, and the characteristics of fish species present in the study area. Further, the PAD identified those fish species that are likely to occur in the study area and, therefore, may be potentially susceptible to entrainment and turbine mortality. The fish assemblage within the study area is comprised of both riverine and diadromous species. For more information regarding the local and transient fish assemblage please see section 4.4.5 of the PAD.

Prior entrainment studies conducted at the Northfield Mountain Project include an entrainment study targeting juvenile American shad in 1992 ([LMS, 1993](#)), a strobe light exclusion efficiency study ([Cook, et al., 1994](#)) and a guide net exclusion efficiency study ([NUSCO, 1999](#)). These studies were conducted to evaluate and mitigate the impacts of the Project operation on anadromous fish species in the Connecticut River. Methods included radio telemetry, entrainment netting, and mark/recapture to investigate the probability of entrainment, and did not investigate turbine mortality.

Downstream juvenile clupeid passage studies at Turners Falls were conducted in the fall of 1991 and 1992 ([Harza & RMC 1992; 1993](#)) which included the objectives of determining the percentage of juvenile shad and herring that pass via the bypass log sluice or that were entrained in the Cabot Station turbines and related data (e.g., catch rates) were compared.

Project Nexus (18 CFR § 5.11(d)(4))

Continued Project operation could potentially affect riverine and migratory fish species that utilize the aquatic habitat within Project area. This study will provide information regarding the local and migratory fish assemblage that is likely to occur in the Project area, and thus be susceptible to entrainment and turbine mortality at the Northfield Mountain Project and Turners Falls Project. This information will provide insight on the effects of continued Project operations to the fisheries resources in the Project area.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The proposed study methodology involves both a qualitative and quantitative approach to estimating entrainment for the Northfield Mountain Project and Turners Falls Project. The qualitative approach will consist of a desktop entrainment analysis, whereas the quantitative approach will be specific to adult and juvenile American shad and adult American eel.

Task 1: Qualitative Assessment of Entrainment and Impingement

A qualitative scale of entrainment potential ranging from “Low” to “High” will be developed for each species or guild recorded within the Turners Falls Impoundment during the baseline fish assemblage assessment ([Study No. 3.3.11](#)). This approach was developed by EPRI ([1997](#)) and provides reasonable seasonal and annual estimated entrainment risk estimates for fishes of three size groups, small (<8”), medium (8-15”) and large (>15”). River resident species composition and length frequency distribution will be derived from fish survey data collected in the Turner Falls Impoundment as part of [Study No. 3.3.11](#).

Assessing the probability of entrainment at the Northfield Mountain Project and Turners Falls Project will include an examination of the characteristics of the Northfield Mountain Project and Turners Falls Project

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

relative to life history and behavioral traits of key species. These factors and various comprehensive reviews of entrainment data ([FERC, 1995](#), [EPRI, 1997](#)) suggest that the following factors will influence the risk of entrainment:

- **Intake adjacent to shoreline:** Near-shore intakes typically entrain fishes at higher rates than offshore intakes, as fish tend to concentrate in littoral areas, and/or follow shorelines or orient to physical structure associated with shorelines.
- **Intake location in littoral zone:** The littoral zone is the most productive region of a reservoir and most fish rear in the shallower littoral areas.
- **Abundant littoral zone species:** Fishes such as centrarchids that spawn, rear, and spend most of their lives in shallow near-shore waters tend to be among the most abundant species in a fish assemblage.
- **Abundant resident clupeids:** Entrainment rates trend highest at projects with clupeids such as gizzard shad and threadfin shad.
- **Presence of obligatory migrants:** Resident fishes are usually entrained relative to their use of near-intake habitat. Migrants into or out of freshwater systems must locate a passage or exit route such as turbine intakes or draft tubes. Such structures provide the flow cues used by migrating fish and may attract such fish if no other flow outlets are present.
- **Shallow intake depth:** Fish are usually more abundant in shallower portions of a reservoir throughout most of the year.
- **Large hydraulic capacity:** More water passed through intakes relative to project inflow will potentially present a higher entrainment risk.
- **High approach velocity:** Approach velocities may positively correlate with entrainment risk. Resident species may become involuntarily entrained if intake velocities exceed their volitional escape swimming speed.

FirstLight will develop a summary of the life history traits and habitat requirements of key resident species as they relate to these factors affecting entrainment at the Northfield Mountain Project and Turners Falls Project. Swimming performance, behavior, and life stages, for example, are factors affecting the entrainment potential of resident species. This process will index which species and lifestages of resident fish are most and least prone to involuntary entrainment. The potential for entrainment of the most susceptible species will be assessed by comparing swim speeds to intake velocity.

Impingement is defined as the involuntary contact and entrapment of fish on the surface of an intake trashracks. Impingement on an intake trashrack may result in injury or death for fish. After determining which fish species have the potential to be present in the area of the intake structures, the sizes of fish species that could physically fit through the existing intake protection devices, based on body dimensions, will be evaluated. An analysis will be performed to estimate the body length of fish that would be physically excluded by the bar rack spacing at each intake structure, and, thus, at risk for potential impingement.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Quantification of Shad and Eel Entrainment and Survival

In addition to the qualitative analysis, FirstLight proposes to quantify entrainment rates of American shad and American eel. Entrainment rates (*i.e.* the percentage of fish entrained through a given structure) will be derived from data collected during proposed tagging studies (Study Nos. [3.3.2](#), [3.3.3](#), and [3.3.5](#)).

Turbine mortality may occur as fish move through hydroelectric turbines; a percentage may be killed due to blade strikes, shear forces, and/or pressure changes. Turbine passage survival studies have been independently performed at numerous hydroelectric projects throughout the country ([Franke et al., 1997](#)). As a result, quantitative turbine mortality estimates can be derived from strike probability equations based on the design characteristics of Project turbines. Suitable source studies will be selected for transfer of turbine mortality data for each Project turbine. Applicable turbine survival data will be obtained from the literature, and associated field data collected from the studies listed above, and used to estimate fish turbine passage mortality. The following turbine characteristics will be used as criteria in this analysis:

- Turbine design type
- Operating head
- Runner speed
- Turbine diameter
- Blade number and spacing
- Peripheral runner velocity

Entrainment loss will be estimated by multiplying fish entrainment rate estimates by turbine mortality rates for both species (and multiple life-stages, where applicable).

Task 3: Reporting

Results will be presented in a summary report, and will be discussed in regards to overall effects to fish populations based upon fish assemblage structure results from [Study No. 3.3.11](#) along with fish passage count data. A tentative table of contents for this study will include:

- Introduction
- Methodology
- Description of Project Features
- Fisheries Community
- Susceptibility to Entrainment and Impingement
- Quantitative Results for American shad and American eel
- Effects of Entrainment and Impingement on Fish Populations
- Conclusions

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort will adequately assess the rate of entrainment and turbine mortality at the Northfield Mountain Project and Turners Falls Project. The proposed approach is consistent with methods accepted by FERC at other hydroelectric projects, such as the Muddy Run Pumped Storage Project (P-2355), Conowingo Project (P-405), Niagara Power Project (P-2216), and the St. Lawrence-FDR Power Project (P-2000); the study will provide information necessary to assess potential impacts of continued project operation on fisheries resources within the study area. The estimated cost for this one-year study effort will be approximately \$50,000 to \$60,000.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. Because a portion of this study draws upon data from radio telemetry and baseline fish assemblage studies, this assessment will be completed upon analyses of the field-based studies.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

3.3.8 *Computational Fluid Dynamics Modeling in the Vicinity of the Fishway Entrances and Powerhouse Forebays***General Description of Proposed Study**

The USFWS, NHFG, MDFW, NOAA, CRWC, and TU requested a study utilizing Computational Fluid Dynamics (CFD) Modeling in the vicinity of the fishway entrances and the powerhouse forebays to evaluate flow field conditions. The Turners Falls Project consists of two hydroelectric facilities, Station No. 1 and Cabot Station, which utilize flow from the power canal to generate power. Migratory and resident fish may reside in the canal throughout the year. Upstream fish passage at the Project consists of three passage structures: the “Spillway ladder” (located at the Turners Falls spillway), the “Gatehouse ladder” (located at the Turners Falls Dam gatehouse), and the “Cabot ladder” (located at Cabot Station). These fish ladders provide an opportunity for upstream passage to migratory and resident fish. Downstream passage at the Turners Falls Project include over the dam, through the powerhouses, or through the downstream fish passage sluice adjacent to Cabot Station. CFD modeling in the vicinity of the fishway entrances and powerhouse forebays is proposed to evaluate flow field conditions.

Bathymetry surveys, required for the CFD models, will be conducted at the Spillway and Cabot fishway entrances and in front of the two powerhouse intakes ([Figure 3.3.8-1](#)). The bathymetric data collected from these surveys will be used to develop three-dimensional CFD models. Once developed, various model production runs will be executed to analyze the hydraulic characteristics (depth, velocity) found in these areas.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The study goal is to use CFD modeling to:

- 1) Obtain information that will assist in designing effective upstream fishways for upstream migrating trust species;
- 2) Reduce impingement, entrainment and delay for downstream migrating fish;
- 3) Direct as many downstream migrating fish as possible towards the uniform acceleration weir and downstream bypass; and
- 4) Maximize the number of upstream migrating fish that find and enter the fishway entrances.

The study objectives are to:

- 1) Conduct bathymetric surveys at the entrances of the Spillway ladder, Cabot ladder, Station No. 1 intake and Cabot intake. FirstLight is not proposing CFD modeling at the Gatehouse ladder as such modeling was recently completed (Alden, February 2012). The Alden report summarizing CFD modeling at the Gatehouse ladder can be found in Appendix F;
- 2) Develop three-dimensional CFD models of:
 - a. The power canal in front of the Station No. 1 powerhouse intakes
 - b. The power canal in front of the Cabot Station powerhouse intakes
 - c. The Cabot fishway entrance

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

- d. The spillway fishway entrance
- 3) Execute production runs (flow scenarios) to understand and evaluate the hydraulics of current (existing) conditions and any changes to:
 - a. Fishway attraction flows;
 - b. Turbine operations; and
 - c. Spill gate operations
 - 4) Develop a series of velocity maps at select discharges. Relative to upstream passage, the CFD modeling will show approach velocities and flow fields that may create a response in fish;
 - 5) The CFD modeling will be coupled with the telemetry study and passage counts to understand which conditions are preferable for guiding migrating fish to the entrances; and
 - 6) With respect to downstream passage, the CFD modeling will provide information on velocities and flow fields in front of the powerhouse intake. At Cabot, the results will indicate whether fish are directed to the surface bypass weir. At Station No. 1 the goal is to have a better understanding of velocity in front of the powerhouse intake.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

This study was requested by NHFGD, MDFW, NOAA NMFS, USFWS, CRWC, and TU. As outlined in their study request letters, the management goals of this study are:

“...to obtain information that will help assist in designing effective upstream fishways for upstream migrating trust species and to reduce impingement, entrainment and delay for downstream migrating fish. CFD models are a relatively cost effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating and which spillway gates are releasing water can all be examined. This study’s results are intended to be analyzed in coordination with the data generated from the telemetry study. The combined analysis from these two data sources can help assess which flow conditions are most advantageous for migrating trust species to enter the fishway under current and proposed conditions.

As for downstream migration of adult and juvenile shad, and adult eel, the results from the models will reveal flow magnitude and direction in front of each powerhouse. Given the limited information that currently exist on survival through Cabot and Station 1, the agency management goal is to direct as many downstream migrating fish as possible towards the uniform acceleration weir and downstream bypass. With respect to upstream passage, it is the goals of the agencies to maximize the number of fish that find and enter the fishway entrances.

Agency study requests are intended to facilitate the collection of information necessary to conduct effective analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 et seq.), and the Federal Power Act (16 U.S.C. §791a, et seq.).”

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

As noted above, a CFD model of the Gatehouse fish ladder at the Turners Falls Dam is completed and can be found in Appendix F. Methodology defined and data collected during this effort will act as supplemental information for FirstLight's CFD modeling. FirstLight believes this recently completed model will be adequate for the required analysis and, as such, is not proposing to develop a new model for the Gatehouse fish ladder. However, additional model runs may be considered using the existing model, if necessary.

Existing GIS elevation data (i.e. contours, DEM, TIN) and Project drawings, combined with field collected data, will be used for the model input. In order to obtain the level of detail required of a three-dimensional model, and bathymetry survey of the study area will be conducted. Data collected during this effort will include: river bed elevation, water surface elevation, water depth, and velocity. Bathymetry data collected will be used for the model input, to calibrate the model, and to validate the model prior to executing production runs.

Project Nexus (18 CFR § 5.11(d)(4))

The Turners Falls Project consists of two hydroelectric stations (Station No. 1 and Cabot Station), a power canal, bypass channel, and dam. In order to provide upstream and downstream fish passage through the bypass channel and power canal fish ladders were constructed at the Turners Falls Spillway, the Gatehouse at Turners Falls Dam, and at Cabot Station. Due to a variety of hydraulic influences related to Project operations and/or naturally occurring hydraulic conditions CFD modeling is required to evaluate potential fish passage barriers in the study area. This study will focus on the hydraulic influences at the Spillway and Cabot Station fish ladders as related to fish passage effectiveness. The Gatehouse fish ladder will not be included in this study due to the fact that a CFD model was previously developed in 2011-2012.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

CFD models will be developed and various production runs will be executed to gain a better understanding of the hydraulic influences and fish passage effectiveness at the Cabot Station and Turners Falls Spillway fish ladders as well as the Station No. 1 and Cabot Station forebays. Prior to development of the models, bathymetric surveys will be conducted at the entrances of the fish ladders and the powerhouse forebays to collect the necessary model input data. In order to effectively meet the requirements of this study, four key tasks have been identified. These tasks include: 1) bathymetric survey of the study area; 2) compile model input datasets in CAD; 3) construct the three-dimensional model; and 4) execute model production runs. These tasks are described in more detail below.

Task 1: Bathymetric Survey of the Study Area

Water surface elevations, water depths, and water column velocities will be collected throughout the study area. For the purpose of this study, the study area will be defined as originating at the fish ladder entrance and extending downstream a predetermined distance. Data will be collected throughout the study reach, including in the forebays, in navigable waters along a number of evenly spaced transects and longitudinal profiles. [Figure 3.3.8-1](#) shows the proposed modeling and data collection locations.

Task 2: Compile Model Input Datasets in CAD

Utilizing existing ArcGIS elevation data and the bathymetry data collected in Task 1, three-dimensional surfaces of the study area river bed will be constructed in AutoCAD Civil 3D. Project drawings will then

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

be used to develop three-dimensional representations of the fish ladders and pertinent Project facilities. Once completed, the three dimensional surfaces and Project facilities models will be compiled into one CAD file (per area) to depict a full physical representation of that area. The composite CAD files will then be used to create the input files for the CFD models.

Task 3: Construct Three-Dimensional Model

The input CAD files developed in Task 2 will be used to build three functional three-dimensional FLOW3D hydraulic models. Once built, various test scenarios will be run utilizing the bathymetry data collected in Task 1. Test scenarios will include model calibration using field collected water surface elevations and model validation using field collected water column velocity data.

Task 4: Execute Model Production Runs

Once the models have been satisfactorily calibrated and validated, production runs utilizing various input parameters will be developed and executed. The results of these model runs will provide a better understanding of potential fish passage barriers resulting from Project operations at various flows, river conditions, and other hydraulic influences.

Task 5. Report

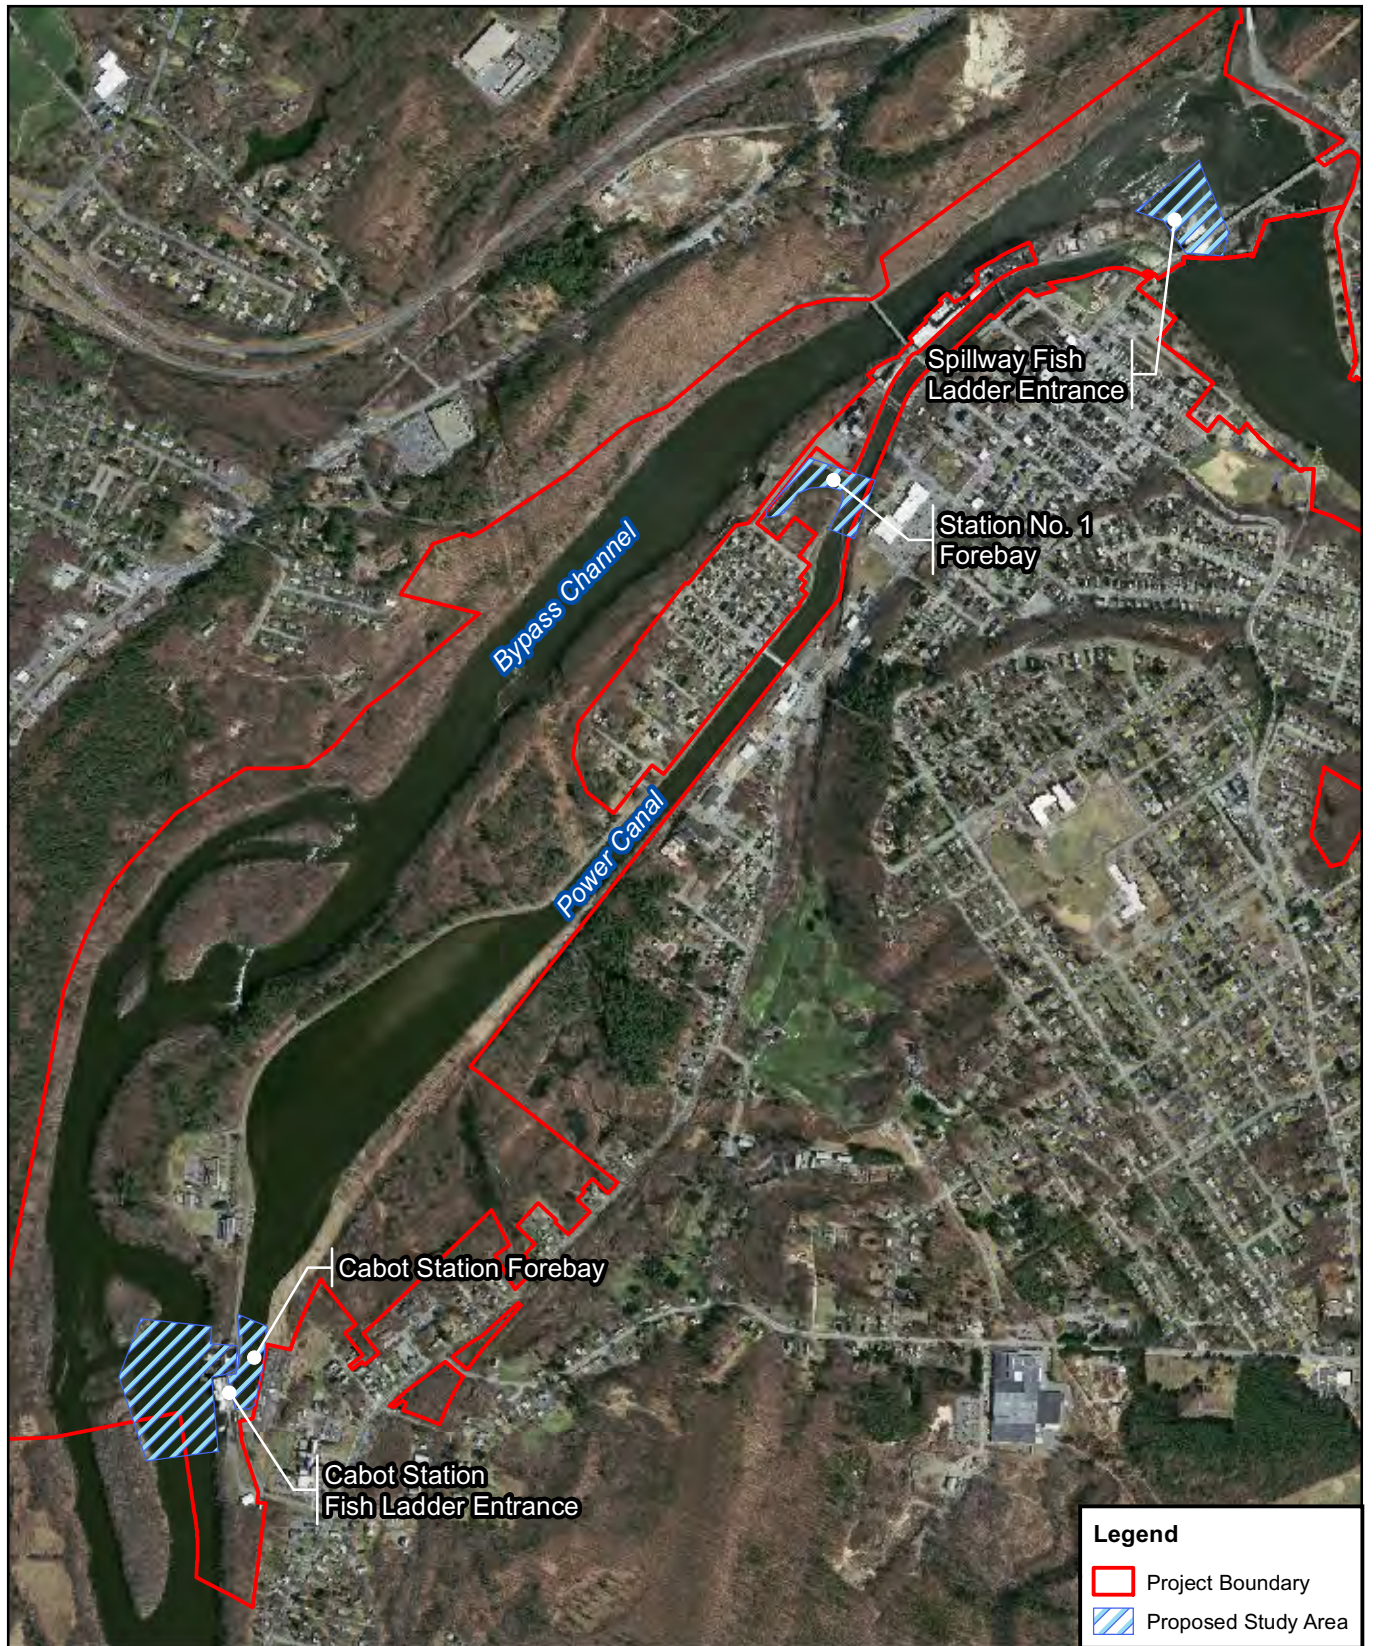

A report will be developed summarizing the findings of the study.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort defined above is adequate to conduct CFD modeling in the study area. Due to the location of the powerhouses and fish ladders along the power canal/bypass channel, three separate bathymetry surveys will need to be conducted and three separate CFD models will need to be developed (Spillway ladder entrance, Station No. 1 forebay, and Cabot ladder/forebay). As such, the total cost to conduct this study is approximately \$200,000 to \$240,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight will conduct this study during the 2014 study year. The bathymetric survey, and any other pertinent field efforts, will be completed during the spring or early summer of 2014 provided there is an adequate amount of flow present in the study reach. Assuming field efforts are completed by early June, data post processing and CAD model development will be completed by mid to late August. Once all model input data has been created, CFD model testing and production runs will occur throughout the fall 2014. All modeling efforts are intended to be complete by the end of the 2014 study year.

**FIRSTLIGHT POWER RESOURCES
PROPOSED STUDY PLAN**

Figure 3.3.8-1: CFD Modeling Locations in the Vicinity of the Turners Falls Power Canal and Bypass Channel

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.3.9 *Two-Dimensional Modeling of the Northfield Mountain Pumped Storage Project Intake/Tailrace Channel and Connecticut River Upstream and Downstream of the Intake/Tailrace.***General Description of Proposed Study**

The USFWS, NHFG, MDFW, CRWC, TU, LCCLC, and the Town of Gill requested similar studies utilizing CFD modeling in the vicinity of the Northfield Mountain Project intake/tailrace channel and in the Connecticut River upstream and downstream of the intake/tailrace to evaluate flow field conditions. The Northfield Mountain Project discharges water from its upper reservoir into the Connecticut River when generating and withdraws water from the Connecticut River to the upper reservoir when pumping. Pumping and generating associated with Project operations utilize the same pipes, at the same location ([Figure 3.3.9-1](#)). To better understand potential Project operations impacts, River2D software will be utilized to conduct two-dimensional modeling of the study area.

In 2007, Woodlot Alternatives developed a two-dimensional model of the Turners Falls Impoundment from Vernon Dam to Turners Falls Dam, including the majority of the proposed study reach. The 2007 Woodlot model was developed using 2006 bathymetry data collected by HydroTerra. A modified version of this model will be used to satisfy the objectives of this study. In order to modify the existing model, new supplemental bathymetry data will be collected in the vicinity of the Northfield tailrace and input into the model. FirstLight will collect the new supplemental bathymetry data as part of this study.

Once the model is updated, various model production runs will be conducted to analyze the hydraulic characteristics (depth, velocity) found in the study area over a range of conditions.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

Goals and objectives of this study are to:

- Model flow characteristics upstream and downstream of the Northfield Mountain Project under existing Project operations (pumping/generating), at several representative river flow levels, and at proposed changes to operations such as those discussed in Section 3.4.4 of the PAD;
- Assess velocities and flow fields at, and in proximity to, the Project intake/discharge structure, when pumping or generating, and their potential to interfere with fish migration;
- Assess the potential for velocity barriers in the mainstem river resulting from pumping and generation flows at the Project, alone or in combination with generation flows from the upstream Vernon Project;
- Assess the potential for Project operations to create undesirable attraction flows to the intake/discharge area that may result in entrainment or delay of migratory fish;
- Assess the potential of a mainstem instream local flow reversal associated with pumping operations to impact migrating fish; and
- Model and then evaluate flow characteristics under alternative Project operations. The alternative operation scenarios will be developed in consultation with the relicensing stakeholders after the initial study results are complete.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

This study was requested by MDFW, USFWS, NHFGD, Town of Gill, LCCLC, CRWC, and TU. The Town of Gill, LCCLC, CRWC, and TU are not resource agencies.

The MDFW, USFWS, and NHFGD all state that the goal of this study is to determine the potential impacts (both project-specific and cumulative) of the Northfield Mountain Project operations (pumping and generating) on the zone of passage for migratory fish near the Northfield Mountain turbine discharge/pump intake, on natural flow regimes in the area of the Connecticut River immediately upstream and downstream of the project, on the potential for entrainment during pumping operations, on the potential for entrainment during pumping cycles that may confuse migratory fish attempting to pass the project, and on bank erosion on both sides of the river in the vicinity of the tailrace.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Project operations data including pumping, generation, water surface elevation, and other pertinent information are currently collected and maintained by FirstLight.

In 2007 a two-dimensional flow model for the Turners Falls Impoundment, including the majority of the study area, was developed by Woodlot Alternatives. Although not originally developed to meet the scope of this proposed study, the data used to develop the original model, combined with updated data where needed, can be utilized to satisfy the goals and objectives previously discussed. As part of the 2007 modeling work, a bathymetric survey of the Turners Falls Impoundment, including the study area, was conducted in 2006 by HydroTerra. The bathymetry data collected as part of that survey, combined with newly collected data in the vicinity of the Northfield tailrace, will be used to update the existing two-dimensional model where required.

Due to the extensive amount of existing information in the study area, FirstLight is not proposing to develop a new two-dimensional model or bathymetric survey. FirstLight instead proposes to review and update the existing model with supplemental field data collection as needed.

Project Nexus (18 CFR § 5.11(d)(4))

The Northfield Mountain Project discharges water during generation and withdraws water during pumping from a channel adjacent to the mainstem of the Connecticut River. Pumping and generating associated with Project operations utilize the same pipes, at the same location. Existing Project operations affect instream flows in this area. Potential impacts of Project operations may include: passage of migratory fish near the pump/discharge area, the potential for entrainment during pumping operations, and the potential for creating flow reversals in the Connecticut River during pumping cycles which may confuse migratory fish attempting to pass the Project.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The 2007 Woodlot Alternatives two-dimensional model will be updated and various production runs will be executed to gain a better understanding of the potential impacts of Northfield Mountain Project operations within the study area. For the purpose of this effort, the study reach will include the Northfield Mountain Project intake/discharge channel and the Connecticut River 1 km upstream and downstream of the channel ([Figure 3.3.9-1](#)). In order to effectively meet the requirements of this study, four tasks have been identified, including: 1) review existing data and identify data gaps; 2) conduct a bathymetric survey of areas identified in Task 1, post process field collected, and post process model input data; 3) build and

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

calibrate the two-dimensional model; and 4) conduct steady-state model runs using River2D software. These tasks are described in more detail below.

Task 1: Review Existing Data and Identify Data Gaps

Input bathymetric data used to create the original 2007 model will be reviewed for accuracy and completeness. All data gaps will be identified to ensure the entire study reach, including the intake/discharge channel, are accurately represented in the final model. Areas found to be lacking adequate bathymetric coverage will be supplemented with newly collected bathymetry data.

Task 2: Bathymetric Survey Update & Post Processing

As part of this study, new bathymetry data in the vicinity of the Northfield tailrace will be collected. Water surface elevations, water depths, and water column velocities will be collected along a number of evenly spaced transects and longitudinal profiles.

Task 3: Build and Calibrate 2D Model

The original model input files and the additional field collected data will be merged into one dataset to build a functional two-dimensional model using River2D software. Once built, the model will be calibrated to existing water surface elevation data. Successful calibration will yield results within ± 0.15 ft of field-measured water surface elevations for at least one calibration scenario.

Task 4: Conduct and Analyze Production Runs

Once the model has been calibrated, production runs representing various operating scenarios will be run. The runs will reflect steady-state hydraulic conditions. The model run results will include two-dimensional water depths and velocities. These outputs can be used to provide a better understanding of potential fish passage barriers resulting from Project operations at various flows, river conditions, and other hydraulic influences.

Task 5. Report

A report will be developed summarizing the findings of the study.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort defined above is adequate to conduct River2D modeling in the study area. The results of the River2D model production runs will provide the data necessary to satisfy the goals and objectives previously outlined. The estimated cost for this study is approximately \$40,000 to \$50,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight will conduct this study during the 2014 study year. Existing data will be reviewed for accuracy and completeness and data gaps will be identified during the late winter, early spring of 2014. All field efforts required to update the existing bathymetry and model input data will be conducted in the spring or early summer provided there is an adequate amount of flow present in the study reach. Assuming field efforts are completed by early June, data post processing will be completed by mid August. Once all model input data has been created, the two-dimensional model will be calibrated and production runs will

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

be executed throughout the fall 2014. All modeling efforts will be completed by the end of the 2014 study year.

3.3.10 Assess Operational Impacts on Emergence of State-Listed Odonates in the Connecticut River**General Description of Proposed Study**

MADFW requested a study investigating the impacts of Project operations on the emergence of riverine odonates, with an emphasis on state-listed species. MADFW requested that these studies be conducted in the upper reservoir, the Turners Falls Impoundment, and a 13-mile reach from the Turners Falls Dam to the Route 116 Bridge in Sunderland. FirstLight is limiting the study area to the Turners Falls Impoundment and 13-mile reach below the Turners Falls Dam. The near-complete lack of a shallow vegetated littoral zone and rocky substrate in the upper reservoir, together with its characteristic water level fluctuations, would likely preclude state-listed odonates (particularly riverine species, which are the focus of this study). The study will include synthesis of existing data, field surveys, and the use of a hydraulic model (see [Section 3.2.2](#)) to assess potential effects of water level fluctuations on factors related to odonate emergence/eclosure behavior.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

This study has two objectives:

5. Synthesis of existing data, supplemented with field surveys, to characterize the assemblage structure and emergence/eclosure behavior of odonates in the project area.
6. Determine if project operations affect the emergence and eclosure success of state-listed odonates, and the potential implications for the odonate assemblage in affected areas, particularly state-listed species.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The Massachusetts Natural Heritage & Endangered Species Program (NHESP), part of the MADFW, is charged with ensuring the conservation and protection of species listed under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) as Endangered, Threatened, or of Special Concern. The resource management goals identified by the NHESP/MADFW are to:

- Ensure that PME measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations.

The MADFW study request is intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, PME measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the Massachusetts Wetlands Protection Act (WPA).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

State-listed Odonate Species Composition: The status of state-listed odonate species is well documented for the Turners Falls Impoundment due to several studies conducted 2001–2010 ([Morrison et al., 2001](#); [2004](#); [2006](#); [McLain et al., 2004](#); [2006](#); [Martin, 2007](#); [2010](#)). Six state-listed species have been observed within reaches above the dam—Cobra Clubtail (*Gomphus vastus*), Stygian Shadowdragon (*Neurocordulia yamaskanensis*), Spine-crowned Clubtail (*G. abbreviatus*), Skillet Clubtail (*G. ventricosus*), Riverine Clubtail (*S. amnicola*), and Midland Clubtail (*G. fraternus*) ([McLain et al., 2006](#)). Cobra Clubtail and Stygian Clubtail are the most abundant state-listed species encountered in this area. In contrast to the Turners Falls Impoundment, survey effort below the dam has been far less intensive; this region of the Connecticut River represents an information gap with regard to rare odonate species composition and abundance.

Based on odonate studies conducted in the Turners Falls Impoundment, as well as both published and unpublished research on the life history and ecology of these species, we have a basic understanding of emergence and eclosure, including when emergence occurs, how high above the water eclosure takes place, how long the process takes, what substrates are typically used, and how these factors differ by species or family groups. To some extent, a thorough review of existing information will provide adequate biological information for an impact assessment using the hydraulic model (see [Study No. 3.2.2 Hydraulic Study of the Turners Falls Impoundment, Bypass Reach and below Cabot Station](#)), but field observations are planned to fill critical knowledge gaps by conducting surveys in both the Turners Falls Impoundment and downstream from the Turners Falls Dam. For example, because much of the odonate research in the Turners Falls Impoundment was initiated due to riverbank stabilization efforts, some habitat types (e.g., the lentic environment near Barton’s Cove) have not been well surveyed for odonates, and the emergence/eclosure behavior of odonates in these different habitat types is not well understood.

Impact of Water Level Fluctuations: It is not well understood the extent to which water level fluctuations disrupt odonate emergence and eclosure. The concern is whether emergent larvae ascend a great enough vertical distance, and quickly enough, to avoid being inundated after eclosure begins. This will depend on a variety of factors, such as the propensity of a species to travel far or climb high, the timing of emergence compared to the timing of water level fluctuations at that particular site, bank slope, and substrate. Related research in the Connecticut River by Martin ([2010](#)) and others ([McLain et al., 2004](#), [2006](#); [Morrison et al., 2001](#)) have investigated the factors that influence the distance nymphs travel before eclosure; air temperature, substrate, and water velocity were among factors identified. Studies have found that coarse substrate on the riverbank, especially riprap, discouraged travel of some odonate larvae. The furthest nymphs were recorded traveling during these studies on any substrate is about 40 feet ([Martin, 2010](#)), but many eclose after traveling just a few feet.

The effect of water level fluctuations on aquatic habitat parameters in the Turners Falls Impoundment and downstream from the Turners Falls Dam is not well documented. A separate study plan is proposed to produce a hydraulic model of these areas (see [Study No. 3.2.2 Hydraulic Study of the Turners Falls Impoundment, Bypass Reach and below Cabot Station](#)).

Project Nexus (18 CFR § 5.11(d)(4))

The timing, rate, and magnitude of releases from the Projects may have adverse effects on state-listed riverine odonate teneral (newly emerged) although the degree of these effects is unknown. In order to fill this information gap, an empirical study is proposed to provide information on the relationship between Project operation and the effects of water level changes on emerging odonate teneral. Results will be used by the MADFW to determine appropriate recommendations to protect and/or enhance state-listed odonates and their habitats.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Review of Existing Information**

Existing information on the species composition of odonates in the proposed study reach of the Connecticut River will be gathered from a variety of sources (see [Literature Cited](#) in this section). The life history and ecology of these species and species groups will be summarized, and significant data gaps related to habitat preference and emergence/eclosure behavior will be identified.

Task 2: Finalize Study Plan and Attain Collection Permit

Because the study is focusing on state-listed odonate species, FirstLight will work with NHESP to finalize the study plan and attain the necessary permit to handle/collect state-listed odonates. FirstLight will comply with the conditions and reporting requirements of the collection permit.

Task 3: Qualitative Surveys for Larvae and Exuviae

Odonate larvae and exuviae will be surveyed between the Turners Falls Dam and the Route 116 Bridge in Sunderland, and in the Turners Falls Impoundment near Barton's Cove, to establish a qualitative baseline for the odonate assemblage in these areas ([Figure 3.3.10-1](#)). Aside from the Barton's Cove area, surveys above the Turners Falls Dam are not necessary due to the intensive survey effort in this area from 2001 to 2010. The survey will be conducted just prior to spring emergence (late May to early June) to maximize detection of all species, under conditions of average to below-average river flows. One representative 200-meter reach will be surveyed in Barton's Cove. Three representative 200-meter reaches will be surveyed downstream from the Turners Falls Dam: one study reach will be located at the confluence of the Connecticut River and the Deerfield River, one will be just upriver of the Route 116 Bridge, and one will be at a location in between (to be determined). Collection methods will include aquatic D-nets or other nets appropriate for conditions at each site, as well as collection of teneral or exuviae on the riverbank (if emergence has started). Collections will be made while wading or snorkeling in shallow water, SCUBA diving in deep water, or while walking along the riverbank. At each site, aquatic, riparian, and upland habitats will be photographed and the following parameters will be recorded.

Aquatic Parameters: water depth, water velocity, dominant substrate types, species composition and coverage of aquatic plants, presence and coverage of fine and coarse organic material;

Riparian Parameters: bank slope, bank height, bank stability, dominant substrate types, plant species composition and cover, tree canopy height, tree canopy density;

Upland Parameters: land use/land cover, dominant vegetation.

Task 4: Quantitative Surveys of Emergence/Eclosure Behavior

Quantitative surveys to determine the emergence/eclosure of odonate species will be conducted at four study reaches. Through consultation with NHESP, two study reaches will be selected from the Turners Falls Impoundment and two will be selected from downstream of the Turners Falls Dam. The specific reaches will be selected to represent a range of aquatic and riverbank habitat conditions and hydraulic characteristics. The two reaches selected in the impoundment will have different habitat than the sites associated with riverbank stabilization that were monitored from 2001 to 2010.

Six transects will be established within each study reach, for a total of 24 transects. Transects will be monumented with PVC pipe or rebar along their length. Each transect will be perpendicular to the river, 1

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

m wide, and will extend upslope approximately 12 m (i.e., the greatest distance recorded in earlier studies of odonate emergence in this area). The following habitat data will be collected at each transect: GPS location of both ends, slope, elevation of the upslope and water ends, elevation of the mean high water mark, types and percent cover of each substrate type, substrate embeddedness, species composition and percent cover of aquatic and upland plants, and anything else noteworthy about conditions at each transect. All transects will be photo-documented. In addition to these transect-specific data, aquatic, riparian, and upland habitat will be characterized for each of the four reaches, as described under Task 3.

Surveys for emerging larvae, exuviae, and teneral adults will be conducted at each transect every two weeks from June through August, and will be timed to coincide with weather and flow conditions that are conducive to emergence, and during times that are generally considered peak emergence periods for odonates that occur in these areas. The time of day, weather, water level, and a qualitative assessment of boat traffic will be recorded at the time of each survey. For each exuvia and teneral found, the emergence distance from the water, elevation, and the structure/substrate it was found upon will be recorded. All exuviae will be collected in individual vials, labeled with site information and date, and preserved for later species identification. If possible, emerging larvae will be watched/tracked as they progress upslope, and the time it takes for them to stop and eclose will be recorded.

Water level data will be used to identify the zones along each transect that have low, moderate, to high inundation frequency. The abundance, density, and species composition of emerged odonates will be compared along a gradient of inundation frequency (taken from water level data). In addition, the influence of water level, habitat characteristics (substrate, vegetation cover, elevation), and weather conditions on emergence distance will be determined using correlation and regression analyses.

Task 5: Water Fluctuation Impact Assessment

A hydraulic model, which will be developed for the whole study area independent of the odonate study, will be used to determine if water level fluctuations affect the emergence and eclosion success of state-listed odonates. The field data gathered during Task 4, particularly the timing (e.g., when species emerge) and distance travelled (both horizontal and vertical) for species and/or species groups will be used in concert with the hydraulic model to determine which species are most vulnerable to fluctuating water levels, and under what conditions they are most susceptible.

Task 6: Report

A report will be prepared describing the survey and modeling methods and results. A tentative table of contents follows:

- Introduction
- Study Area
- Methods
 - Larval Surveys
 - Exuvia Surveys
 - Water Level Impact Assessment
- Results
 - Larval Surveys
 - Exuvia Surveys
 - Water Level Impact Assessment
- Discussion
- Conclusions

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Literature Cited

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The methods and analyses proposed are consistent with other studies of this nature, and build upon knowledge gained from other studies to focus specifically on the effects of water level fluctuations. The estimated cost for this study may range from \$40,000 - \$60,000 (not including the hydraulic modeling completed as a separate study). Task 3, which can be considered a first phase of fieldwork that would inform the quantitative surveys, would cost in the range of \$8,000 - \$10,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

Field work for this study will occur in 2014. A final study plan for the quantitative survey and hydraulic/habitat analysis would be developed in cooperation with NHESP.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

3.3.11 Fish Assemblage Assessment**General Description of Proposed Study**

In the study request letter from the FERC, a baseline fisheries population study was requested. The request included sampling within the Turners Falls Impoundment, tailwater areas, the bypassed reach, and downstream riverine corridors via electrofishing surveys. The FERC also requested targeted eel sampling of upstream and downstream migrating American eel. Targeted eel sampling will be conducted as part of [Study No. 3.3.4 – Evaluate Upstream Passage of American Eel at the Turners Falls Project](#) and silver-phase eel abundance and migration will be evaluated in [Study No. 3.3.5 – Evaluate Downstream Passage of Eel](#); thus, additional targeted eel sampling is not being proposed for this study.

In their study request letters, USFWS, MADFW, NHFGD, CRWC, Town of Gill, TNC, TU, VANR each requested a fish assemblage assessment to determine the occurrence, distribution, and relative abundance of fish species within the project areas and to compare study results to historical records. They requested a comprehensive assessment of fish assemblages, employing multiple gear types to randomly sample a variety of habitats throughout the study area during spring, summer, and fall as part of a robust sampling design. The proposed study will include a statistically rigorous and comprehensive stratified-random design similar to what has been used successfully on large rivers a high degree of spatial heterogeneity ([Kiraly, 2012](#)).

MADFW further requested that the study include state-listed fish species as well as host fish species of the Dwarf Wedgemussel (*Alasmidonta heterodon*), federally- and state-listed as “Endangered”; the Yellow Lampmussel (*Lampsilis cariosa*) state-listed as “Endangered”; and the Eastern Pondmussel (*Ligumia nasuta*), state-listed as “Special Concern.” MADFW requested that the study should assess the occurrence and abundance of mussel larvae on resident host fish. FirstLight is not proposing to evaluate mussel larvae on host fish because the relationships are already well understood ([Table 3.3.11-1](#)); The level of effort proposed will provide data on the distribution and relative abundance of state-listed fish species and host fish species.

The PAD for the Turners Falls Project and Northfield Mountain Projects identifies 22 species of fish that occur in the aquatic habitat within the Project boundary. The study described herein, will document fish species occurrence, distribution and relative abundance within the Turners Falls Project and Northfield Mountain Project areas. FirstLight believes that the level of effort will provide baseline fish assemblage data and that the overall sampling design will provide useful data that can be used to inform other proposed studies.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to provide baseline information pertaining to the fish assemblage structure within the study area. Specific objectives include:

- Document species occurrence, distribution, and relative abundance of resident and diadromous fish within the project area along spatial and temporal gradients.
- Describe the distribution of resident and diadromous fish species within reaches of the river and in relationship to data gathered by the Aquatic Habitat Mapping Study.
- Compare historical records of fish species occurrence in the project area to results of this study.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The MADFW, NHFGD and the VTFWD each have, as a mission, the protection and conservation of fish and their habitats. Riverine fish species are an important component of the river's ecology and are the basis for the sport fishery. Furthermore, several of the states' SGCN have been documented in the project area.

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the MADFW. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that PME measures are commensurate with Turners Falls Project and Northfield Mountain Project affects and meet MESA requirements for the Turners Falls Projects and Northfield Mountain Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Turners Falls Project and Northfield Mountain Project operations.

The agencies requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, PME measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA. Specific to state-listed fish and mussel species, the Divisions goals are to:

- Protect, enhance, or restore diverse high quality aquatic habitats in the Connecticut River watershed and mitigate for the loss or degradation of these habitats.
- Minimize current and potentially negative effects of Turners Falls Project and Northfield Mountain Project operations on state-listed species and their habitats.

Determining species occurrence, distribution, and abundance of fish species will better clarify what species occur in the project area both spatially and temporally relative to habitats which may be affected by operation of the Turners Falls Project and Northfield Mountain Project. This information will better inform results from other study requests that will be examining the effects of operations of the Turners Falls Project and Northfield Mountain Project on various aquatic habitats, water quality, and other related concerns such as entrainment concerns at the Northfield Mountain Project. This information will be used to make recommendations and provide full consideration for all species, including those that might not otherwise be known to occur in the project area and impacts that may affect their population status through direct or indirect effects of the Turners Falls Project and Northfield Mountain Project.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

A study of resident fish species in the Turners Falls Impoundment was conducted by the Commonwealth of Massachusetts from 1971 to 1975. Eight stations in the impoundment were sampled every other week from April through October with electrofishing equipment ([MDF&G, 1978](#)). Because many changes have occurred throughout the watershed during the last four decades, these data may not be an accurate representation of the current fish assemblage.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

In 2008 the impoundment was surveyed via electrofishing; this survey, conducted by Midwest Biodiversity Institute (MBI), was part of a larger USEPA effort to sample the entire Connecticut River from its headwaters at Lake Francis to the freshwater extent of the tidal estuary (Yoder et al., 2009). The 2008 survey did not have the same goals and objectives as this study; thus, data collected is not sufficient to assess the abundance, occurrence, or distribution of fish within the study area or in relation to project operations. Neither study employed the use of alternative gear types; while electrofishing is considered to an effective method for capturing fish in littoral areas of flowing water, capture probabilities are typically lower for small fish or those lacking swim bladders. It is also not effective at capturing fish from deep water unless modified. A total of 22 fish species were identified in the project area based on historical data, but several species reported to occur within the project area were not documented, including northern pike, burbot, eastern silvery minnow, and channel catfish.

As referenced in the PAD, Section 4.4, two state-listed fish species are known to occur in the Connecticut River, including the Eastern silvery minnow (*Hybognathus regius*) and burbot (*Lota lota*), both of which are state-listed as “Special Concern.” Currently, there are only two known populations of the Eastern silvery minnow in Massachusetts, both located in the Connecticut River. Burbot are also rare in Massachusetts, with only a few individuals having been collected in the Connecticut River watershed.

The tessellated darter is one of only three fish species in the Upper Connecticut River that serve as hosts for the glochidia of Dwarf Wedgemussel, the others being the slimy sculpin (*Cottus cognatus*) and the Atlantic salmon (*Salmo salar*) (Nedean, 2008). Tessellated darters are a relatively sedentary benthic insectivorous fish with small home ranges and short, fast bursts of speed.

Based on data collected by Yoder (2009), sampling at 4-5 transects distributed throughout the Turners Falls Impoundment was sufficient to capture most but not all species detectable by electrofishing the shoreline of the impoundment (Figure 3.3.11-1); a closer inspection via rarefaction of individual transects surveyed indicates that the number of fish captured at some transects may not have been high enough to document most species within a reach (Figure 3.3.11-2). Based on the rarefaction curves from all transects electrofished, a minimum of 100 fish per reach would ensure that most species within a reach were captured, but four out of the five transects electrofished contained a sample of less than 150 fish (N = 9-75), with only one containing a sample greater than 150 fish (N = 580). This may have been due to too little sampling effort within a reach and/or that the transect may not have been representative of the entire reach. Therefore, effort per reach in the Turners Falls Impoundment needs to either be 1) greater than 1.0 km of shoreline sampled; 2) conducted along more than one transect to account for spatial heterogeneity within a site; or 3) performed with a combination of greater total sampling effort divided among a greater number of spatial replicates. While the study design proposed is different than from Yoder (2009), those data provide a starting point with which to estimate the level of electrofishing effort required for precise estimates of relative abundance that includes most species within a river reach.

Project Nexus (18 CFR § 5.11(d)(4))

Operation of the Turners Falls Project and Northfield Mountain Project has the potential to directly affect fish populations, biological interactions, and habitat quantity and quality. For example, headpond and tailwater water level fluctuations could dewater spawning areas, limiting productivity of certain fish species through direct impacts to their spawning success, ultimately resulting in alterations to fish assemblage structure. An understanding of the current fish assemblage is needed in order to examine potential effects. Determining species distribution and abundance will clarify what species occur in the Turners Falls Project and Northfield Mountain Project areas, spatially and temporally, relative to habitats that may be affected.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The study area includes the Connecticut River from the upstream reaches of the Turners Falls Impoundment to approximately five miles downstream of Cabot Station and will be divided into six strata ([Figure 3.3.11-3](#) and [Table 3.3.11-2](#)). Strata on the Connecticut River will be delineated based on a combination of general river morphology, project structures, and size in order to incorporate spatial variability into the sampling design (see [Kiraly, 2012](#)). Within each stratum, a minimum of three randomly selected locations will be sampled via boat electrofishing and trap netting during the early summer and again in the fall. Early summer sampling will be performed when spawning anadromous species are present; fall sampling will be performed when most juvenile fish are large enough to sample. Due to the high degree of variability in water level and flow, different locations will be sampled during each sampling event rather than sampling at the same locations multiple times. This process avoids any time-related, site-specific bias that could be introduced at sampling locations due to habitat changes between surveys; analyses will therefore be performed at the stratum level rather than the sampling-location level.

Task 1: Sampling Location Selection

Prior to field sampling, shorelines within all strata will be delineated into 500 meter segments using ArcGIS. Randomized lists will be created for all sites within each stratum; this will allow field surveyors to randomly select alternative sampling locations in the event of a site being inaccessible or otherwise impossible to sample.

Task 2: Fish Capture

Daytime boat electrofishing will be conducted along a minimum of three randomly selected 500 meter transects within each stratum. Boat electrofishing can effectively sample fish from most near-shore littoral habitats present within the Connecticut River. If fewer than 150 fish are collected among all three transects combined within a stratum, additional random transects will be electrofished until a 150 fish sample is exceeded. This will ensure that most species within a stratum that are detectable by electrofishing are captured; because areas with low fish density require less time to sample than areas with high fish density, additional sampling due to low densities of fish encountered is not expected to increase the level of field effort by personnel, and the randomized selection of additional sites will improve precision without adding bias. Boat electrofishing effort will be standardized to distance (km) and time (s) of electrofishing.

Trap nets can be used to sample mobile species, including those that reside in areas too deep and/or too far from shore to effectively capture via electrofishing; thus, trap netting surveys will be used to supplement boat electrofishing data. Trap netting will be conducted at suitable locations along transects selected for electrofishing; the exact location of net placement will be determined in the field, with the intent to sample areas containing depths greater than 8 feet, if present. Trap nets will be placed perpendicular to shore and set overnight (approximately 8 hours); one trap net will be fished per 500 meter transect (a minimum of three per stratum). Trap netting effort will be standardized by net-hours.

All fish captured will be identified to species, measured (total length), weighed, and released; if large numbers ($n > 25$) of small fish are captured, they will be grouped by size class, enumerated, and batch-weighed with length measurements only taken from one large and one small representative specimen within each group. Digital photographs will be taken to document species that may be difficult to identify in the field, such as cyprinids.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

In addition to biological data, supporting data will also be collected for each sample site including: location (GPS), sampling gear type, sampling effort (soak time and/or seconds fished), mesohabitat type, average depth, average velocity, river flow, water temperature, predominant substrate, time of day, day of year, presence of cover, and proportion of vegetation cover. All data will be recorded on dedicated data sheets. Upon return from the field, data sheets will be reviewed for quality assurance and archived.

Task 3: Data Analysis and Reporting

Catch per unit effort (CPUE) will be calculated for each species, stratum, and sampling technique. Values of CPUE for each segment will be calculated as the sum of catch from all samples within a stratum divided by the sum effort expended within that stratum. The CPUE, effort will be consistent among samples, thus sample standard error will be calculated to determine confidence intervals in order to facilitate comparisons among strata and season. Additionally, if both sampling designs are used consistently and in the same manner among all strata, whole-sample CPUE will be calculated by combining electrofishing and trap netting data and dividing by the number of locations sampled; this will allow direct comparisons of all data among strata.

Information collected during this study will be compiled and presented in a final report. The report will include a map of the study area and will depict the location of sample sites and contain results for fish species occurrence, distribution and relative abundance. Comparisons will be made with historical records. Results will be described in relation to studies described in study plans [3.3.14](#) – *Aquatic Habitat Mapping of the Turners Falls Impoundment* and [3.3.13](#) – *Impacts of the Turners Falls Project and Northfield Mountain Project on Littoral Zone Fish Habitat and Spawning Habitat*.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort will adequately address the objectives by documenting fish species occurrence, distribution and abundance within the project area along spatial and temporal gradients. FirstLight estimates the cost of this study to be \$55,000 to \$75,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The study described herein is scheduled to be conducted in the summer and fall of 2014, with Task 1 occurring prior to field studies.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.3.12 Evaluate Frequency and Impact of Emergency Water Control Gate Discharge Events and Bypass Flume Events on Shortnose Sturgeon Spawning and Rearing Habitat in the Tailrace and Downstream from Cabot Station***General Description of Proposed Study**

In their study request letters, the USFWS, NMFS, NHFGD, and CRWC each requested a study to assess the impact of sediment disturbance and excessive velocities resulting from emergency water control gate discharge and bypass flume spill events on shortnose sturgeon spawning and incubation habitat in the Cabot Station tailrace and downstream areas.

This study is a field assessment of water velocity and sediment transport conditions during spillage events at Cabot Station to describe potential impacts on shortnose sturgeon and to inform potential mitigation.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to determine appropriate scenarios for operation of the emergency water control gates and bypass flume that will be sufficiently protective of shortnose spawning and rearing below Cabot Station from excessive water velocities and exposure to abrasive sediments dislodged and transported across spawning and rearing areas.

The objectives of the study are to:

1. Determine the frequency that the emergency water control gates are operated to discharge large quantities of water.
2. Understand the operation of the bypass flume that results in bypass flume spill events.
3. Evaluate the impact of these events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot Station.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The USFWS and NMFS seek to understand current emergency water control gate and bypass flume operations and associated impacts to determine potential operation scenarios that avoid or minimize negative effects on shortnose sturgeon spawning and rearing.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

During monitoring of shortnose sturgeon spawning, researchers at the S.O. Conte Anadromous Fish Research Center [Conte Lab] have observed spillage at the emergency water control gate and the bypass flume that increased velocity over the rearing area downstream of Cabot Station and may have also resulted in a debris plume ([Kieffer and Kynard, 2007](#); [Kynard et al., 2012](#)). The frequency of these events has not been studied, nor has the impact on shortnose sturgeon spawning and early life-history stages.

Ten gates are present at the Cabot spillway, two of which are used for attraction flow at the Cabot Fishway. The Cabot spill gates open automatically if the forebay water surface elevation gets too high to prevent emergency overtopping of the power canal. The gates will also open if changes in elevation indicate that a canal breach may have occurred. Operators can intervene manually when it is necessary to partially open a gate to help move debris off the trash boom.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

The bypass flume is utilized as a downstream fish passage facility at Cabot Station and is generally open for fish passage from April through mid-November in accordance with a schedule provided by CRASC. The bypass flume (also referred to as the log sluice) can also be used to pass debris downstream.

Data are available from FirstLight from 2008-2012 regarding the timing and magnitude of gate openings for both structures; however, no data exist that relate operations to potential impacts on sturgeon spawning and rearing such as bottom velocities and sedimentation rates.

Project Nexus (18 CFR § 5.11(d)(4))

One of the two critical shortnose sturgeon spawning and rearing areas in the Connecticut River is located within the Cabot Station tailrace, within an area impacted by project discharges ([Figure 3.3.12-1](#)). Spillage events through the emergency water control gates and bypass flume have been observed to create flow dynamics that may not be sufficiently protective of shortnose sturgeon spawning and rearing in this area. Results of this study will provide recommendations for operation of the emergency water control gates and the bypass flume that will avoid or minimize sedimentation and improve bottom velocities that are sufficiently protective of shortnose sturgeon spawning and rearing.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The design of this study will document potential impacts of spillage at the emergency water control gates and the bypass flume at Cabot Station on shortnose sturgeon spawning and rearing through field verification of conditions to which spawning and early life history stages of sturgeon are exposed. These methods will evaluate a variety of flow conditions, and will attempt to separate the effects of releases at the emergency water control gates and the bypass flume through the use of control locations upstream. This study will be performed on simulated events, which will be evaluated concurrently with the instream flow study and associated bypass reach flow scenarios, as timing and schedule dictates. Flow scenarios and associated measurements will be performed separately for the emergency water control gate and the bypass flume, and will be evaluated during the fall to avoid impacts to sturgeon spawning.

Task 1: Analysis of Existing Data and Scenario Development

To evaluate the frequency of spill events at different magnitudes during sturgeon spawning and rearing, operations data provided by FirstLight of gate opening levels will be analyzed. Time series data during April 15th through June 22nd from 2008-2012 for both the emergency water control gates and the bypass flume will be plotted and examined to determine the appropriate number and gate opening values of spill categories for further analysis.

Frequent spill events will then be categorized into separate routine operating and/or maintenance scenarios; emergency scenarios will not be evaluated in this study because changes in operation during emergency events are not anticipated by FirstLight. Routine operating and maintenance scenarios that involve spillage will be agreed upon prior to field work and will include various combinations of up to three flows through the emergency water control gates and the bypass flume tested separately under two bypass flow rates, and two generation flow rates for a total of up to 12 total scenarios for each of the spill locations.

Task 2: Field Verification of Conditions

Simulated events, with spillage rates described by Task 1, will be evaluated in the field by measuring bottom velocity and capturing sediment. To quantify bottom velocities at the known sturgeon spawning/rearing area (see [Kynard et al., 2012](#)), a sample of ten random locations within the spawning

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

area will be selected where the average water velocity will be measured at 1.5 feet from the bottom for 30 seconds. Additionally, average velocities will be measured in the same manner at ten random locations within the same area and under the same river flow and operational conditions, except in the absence of spillage.

To quantify sediment transport, it is envisioned that five bottom-set drift nets will be placed at random locations within the known spawning/rearing area (*see Kynard et al., 2012*); mesh size and soak time will be determined in collaboration with resource agencies and the Conte Lab. Velocity measurements will be taken at the mouth of each net upon setting, spillage stabilization, and removal to aid in calculations of volume of water sampled. As a control, three nets of the same design will be placed in random locations on a shoal upstream of Cabot Station determined to be distant enough from spillway locations to be independent from spill effects; spill has been documented to induce temporary flow reversal during low discharge (*Keiffer and Kynard, 2007*). Samples will be strained of large-sized organic material, visually inspected, and categorized to evaluate general content, photographed, and delivered to a laboratory for subsequent analysis of dry weight.

Task 3: Data Analysis and Reporting

Descriptive statistics (mean, standard error) of measured variables will be calculated. Multiple linear regression and analysis of variance (ANOVA) will be used to determine whether conditions measured at the sturgeon spawning and rearing area are correlated with and differ significantly among spillage levels, and to determine whether and/or how covariates such as river flow or spillway operational status affect the results.

If spillage at Cabot Station is found to increase the amount of sediment flowing over the sturgeon spawning area, results from this study will be compared to the 2-D hydraulic model developed during the instream flow study in order to assess a broader range of potential mitigation measures.

A preliminary report containing results will be presented after the 2014 sampling data are collected and analyzed; if river flows are conducive for evaluating all proposed scenarios during 2014, then all field data collection will be performed during 2014 and the data analysis and a final report will be completed by late 2014. In the event that river flows are not conducive to evaluating all flow scenarios, a preliminary report will be provided during late 2014, field work will also be performed during 2015, with a final report that includes comparisons with hydraulic model results prepared by late 2015.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of spillage at Cabot Station on sturgeon spawning and rearing habitat. The estimated cost for this study is approximately \$35,000 to \$45,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

Existing data will be analyzed prior to field work. Field work will be performed during 2014 and potentially during 2015 if river flow is not conducive for evaluating all scenarios. The final report will be submitted during late 2015.

*3.3.13 Impacts of the Turners Falls Project and Northfield Mountain Project on Littoral Zone Fish Habitat and Spawning Habitat***General Description of Proposed Study**

In their study request letters, the USFWS, NHFG, MDFW, VTDEC, Town of Gill and CRWC each requested a study of the impacts of the Turners Falls and Northfield Mountain Projects on littoral zone fish spawning and spawning habitats. FirstLight proposes a study to determine if project operations and water level fluctuations in the Turners Falls Impoundment negatively impact anadromous and resident species and to determine if negative impacts are occurring so that appropriate mitigation measures may be developed, if warranted, to protect and conserve the species utilizing project waters. Fish that may be potentially impacted includes sea lamprey, white sucker, fall fish, smallmouth bass, yellow perch, spottail shiners, bluegill, black crappie, chain pickerel, northern pike, common sunfish, and walleye. A study plan to assess sea lamprey spawning within the Turner Falls and Northfield Mountain project areas can be found in Section 3.3.15. This study will focus on the resident populations of temperate basses, perches, suckers, minnows and pike/pickerels in the Turners Falls Impoundment. Additional information relevant to this study will be obtained from other proposed studies, including the fish assemblage ([Section 3.3.11](#)), habitat mapping ([Section 3.3.14](#)), and tributary access ([Section 3.3.17](#)) studies.

It is anticipated that this study will occur during the spring and early summer of 2014 when the resident species typically spawn. Should river discharge or temperature during this period prove to be atypical (e.g., outside of 25-75th percentile of average weekly flows/temp), then FirstLight will consider repeating the study in 2015 to ensure representative conditions occur during sampling to reduce bias in observations.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to determine if project operations negatively impact fish species so that appropriate mitigation measures may be developed, if warranted, to protect and conserve the species utilizing project waters.

Specific objective of this study are to:

- Assess timing and location of fish spawning in the littoral zone.
- Delineate, qualitatively describe (e.g. substrate composition, vegetation type and relative abundance), and map shallow water habitat types subject to inundation and exposure due to project operations.
- Evaluate potential impacts of impoundment fluctuation on nest abandonment, spawning fish displacement and egg dewatering.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals identified are to:

1. Maintain, restore, and recover populations of species of conservation and management concern to self-sustaining levels.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

2. Maintain and restore the ecological composition, structure, and function of natural and modified ecosystems to ensure the long-term sustainability of populations of species of conservation and management concern.
3. Protect and conserve fish and their habitats.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Resident fish species, as well as anadromous species, identified in project waters are discussed in Sections 4.4.2-4.4.4 of the PAD. Under the FERC license, the Turners Falls Impoundment elevation may fluctuate between 176.0 ft msl and 185.0 ft msl, as measured at the Turners Falls Dam. Additionally, a bathymetric map of the Turners Falls Impoundment based in field data collection in July 2006 was developed by Hydroterra Environmental Services, LLC (see Figure 3.2.1-4 of the PAD) is available for reference.

Project Nexus (18 CFR § 5.11(d)(4))

Project operations have the potential to impact fish species by influencing spawning success and spawning habitat quality and quantity. For example, water level changes due to Project operations could create conditions where fish eggs are exposed to air, where spawning habitat is dewatered, and/or where fish abandon nests containing eggs.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

Information and data obtained through the proposed the fish assemblage study (Section 3.3.11), aquatic habitat mapping study (Section 3.3.14), and tributary access (Section 3.3.17) study will likely be used to address some of the objectives of this study.

FirstLight anticipates that this study will be conducted in the spring and early summer of 2014.

Task 1: Literature Review

Prior to conducting the field investigation, a desktop literature review will be performed to determine when resident species known to occur in the Turners Falls Impoundment typically spawn. In addition to the timing of spawning, the literature review will also be helpful for identifying typical habitat-types used by resident species for spawning, as well as spawning behavior or habits to aid in subsequent field identification.

Task 2: Field Surveys

Once spawning periods have been identified, the field survey effort will be scheduled to maximize potential observations of different species spawning activities. FirstLight anticipates a minimum of two surveying events (one in early spring and one in early summer) to capture of the spawning periods of the resident species. The exact number of surveys will be determined upon completion of the desktop literature review of Task 1.

Considering the impoundment elevation may fluctuate up to nine feet due to project operations, to the extent practical, attempts will be made to conduct this study of the littoral zone when conditions are close to the minimum water surface elevation of 176.0 ft msl to ensure all areas impacted by project-related water level changes are readily observable. For the purpose of this investigation, the littoral zone will be considered the area extending from the edge of the water line at the shore out to a depth of approximately six feet. This will be a general guideline, as the observable characteristics of the littoral zone can vary

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

with water clarity, water level, time of day, and the prevailing weather conditions. The areas typically wetted when the impoundment is at the maximum allowable water surface elevation (El. 185.0') will also be observed during the field survey(s). Additionally, tributaries identified in PSP 3.3.17 as accessible during spawning seasons will be observed during the field surveys.

Assuming the water clarity is conducive for visual assessment, field sampling will be conducted by systematically traversing the littoral zone (depth < 6 feet) of the Turners Falls Impoundment via boat and/or foot (wading) to visually identify any fish nests, egg masses/deposits, and/or spawning habitat. Additional necessary equipment and data collection will include:

- a digital camera for photo-documentation of habitat types, egg deposits, and identified nests;
- an underwater Atlantis™ Panning Camera to identify spawning nests/habitats in those instances where they cannot be easily identified from the surface;
- a handheld GPS unit to geo-reference the locations of identified habitats, egg deposits, and nests;
- a handheld water quality meter to measure water temperature;
- a Marsh-McBirney flow meter to measure velocity at identified spawning habitats, egg deposits, and nests;
- a secchi disk to estimate water clarity;
- a stadia rod and/or depth meter for recording depth of identified spawning habitats, egg deposits, and nests; and
- data sheets for recording water quality parameters, general observations, weather conditions, and other relevant descriptive information (e.g., sediment/grain sizes associated with nests, approximate diameter of identified nests, presence of fish at nests, presence of aquatic vegetation, nest abandonment, etc.).

These data will be recorded on standardized, waterproof field data sheets. Upon completion of the field survey, all data sheets will be reviewed for quality assurance. Data necessary to develop a map of the observed spawning habitat, egg deposits and fish nests relative to the areas subjected to dewatering due to project operations will be electronically transcribed. A report containing a discussion of the impacts of water level fluctuations on the resident species spawning and spawning habitat, including potential nest abandonment, spawning fish displacement and egg dewatering, in the Turners Falls Impoundment will be produced.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Northfield Mountain Project and Turners Falls Project on fish spawning and spawning habitat in the investigation area. The estimated cost for this one-year study is approximately \$30,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

FirstLight anticipates that this study will be conducted in the spring and early summer of 2014, after high spring flow conditions have subsided.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.3.14 Aquatic Habitat Mapping of Turners Falls Impoundment**General Description of Proposed Study**

FERC requested aquatic habitat mapping of the Turners Falls Impoundment, which compliments requests by other stakeholders as described in Study Nos. [3.3.13](#), and [3.5.1](#). FirstLight proposes to conduct a habitat field survey to delineate aquatic littoral and demersal habitat in terms of substrate and cover in the Turners Falls Impoundment.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The purpose of the study is to map the distribution and abundance of aquatic habitat within the Turners Falls Project impoundment in the Connecticut River, evaluate the types of aquatic habitats that occur there, and identify any potential effects of operations of the Turners Falls Project and Northfield Mountain Project on this habitat. The habitat mapping and accompanying characterization of aquatic mesohabitat will provide essential information regarding the character and extent of aquatic habitat that may potentially be affected by Project operation. The quantified spatial data generated by this survey will help to provide a framework for upcoming data analysis efforts relative to operations and impoundment modeling.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The FERC must decide whether to issue a new license to FirstLight for the Turners Falls and Northfield Mountain projects in the Connecticut River. Any license issued shall be best adapted to a comprehensive plan for improving or developing a waterway or waterways for all beneficial public uses. Aquatic habitats in the Connecticut River support a sustainable riverine ecosystem that provides public opportunities, including a sport fishery. Ensuring that the effect of project operations pertaining to this resource is considered in a reasoned way is relevant to the Commission's public interest determination.

Several resource agencies have submitted applicable management goals in their study request letters. Resource management goals for this study are consistent with those identified in [Study No. 3.5.1](#) *Baseline Inventory of Wetland, Riparian and Littoral Habitat in the Turners Falls Impoundment, and Assessment of Operational Impacts on Special-Status Species*.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

No prior habitat mapping information is available to document the habitat resources of the Turners Falls Impoundment. Mapped locations of aquatic habitats in the Turners Falls impoundment is needed to evaluate the potential influences of the Turners Falls and Northfield Mountain Project on aquatic resources.

Project Nexus (18 CFR § 5.11(d)(4))

Water levels in the Turners Falls impoundment fluctuate due to operations of the Turners Falls Project and because the impoundment also serves as the lower reservoir for the pumped-storage operations of the Northfield Mountain Project. As a result, littoral aquatic habitat and aquatic species that utilize the habitat may be affected by water level fluctuations. This study will establish a baseline condition and the health of the aquatic habitat and aquatic species of the Connecticut River in the Turners Falls Impoundment under current operations.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

FirstLight proposes to map the distribution and abundance of littoral aquatic habitat within the Turners Falls Project impoundment in two phases. During the first phase, major aquatic habitat types will be delineated. During the second phase detailed microhabitat data will be collected on representative transects. These data will then be used in conjunction with operational and other models to evaluate project effects on aquatic resources in the study area.

Task 1: Field Survey

Lentic aquatic habitat suitability is defined primarily by substrate, cover and depth. Each of these habitat parameters will be assigned specific attributes to be used for field delineation. These will generally include:

- **substrate:** fines (sediment, organic detritus, mud, etc.), sand, gravel, cobble, boulder, bedrock, rubble
- **cover type:** object cover (*i.e.* boulder, woody debris, riprap, etc.), overhead cover (overhanging limbs, structures, etc.); vegetative cover (emergent, submerged)
- **cover density:** absent, low, moderate, high
- **depth (at normal pool):** surface to substrate (ft)

Task 1a: Delineation

Delineation of the 20-mile-long impoundment will be conducted by boat and will occur during summer during a period of relatively stable impoundment levels so that aquatic vegetation is established, and so that observations of depth relative to substrate and cover can be observed under consistent conditions, to the extent practical.

Habitat delineation will be conducted by a boat traveling through the littoral zone parallel to shore. The prevailing water elevation at the beginning of the survey will be documented by bench-marked survey. Staff gages will be established throughout the study area so that changes in water elevation during the survey can be accounted for. The field crew will methodically record habitat attributes and geo-reference with GPS each boundary where a pronounced change in substrate and/or depth occurs. We anticipate that cover will occur in patches rather than broad linear boundaries. Therefore, a centroid GPS waypoint will be collected at key cover nodes.

Additional relevant biological and geomorphic characteristics will also be collected where appropriate including readily observable aquatic fauna; channel geometry (including bank and shoreline slope); etc. The data will be recorded on data sheets, a dedicated field book, or via a pentop computer. Upon completion of the survey, all data will be rechecked for quality control and archived.

Task 1b: Microhabitat

Transect data will be gathered within representative littoral areas. The distribution and number of transects will be dictated by the variability detected during the delineation phase, but the goal would be to have one transect accounting for each major type of shoreline slope/littoral substrate/cover/depth condition documented during delineation. Each transect will extend from El. 185' to El. 176' and include the area to a water depth of approximately six feet. Verticals will be located along each transect to depict the following elevations:

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- top of bank
- normal high water
- upper elevation of pool (if different than normal high water)
- normal pond elevation
- toe of bank
- elevation 6 ft below normal low pool elevation.

Additional verticals will be established at intervals wherever micro-changes in slope, substrate embeddedness, or cover are encountered. Elevations will be surveyed in project datum so that data can be integrated with other project operation data for analysis. The locations of all transects will be geo-referenced with GPS and transect headpins marked with blazing.

Task 2: Analysis and Report

Geospatial mesohabitat data will be transferred to a GIS format and used to develop both visual maps depicting distribution as well as tabular information quantifying the abundance and distribution of habitat features in the study area. A summary report will be developed that will include survey methods, GIS maps showing the mesohabitat spatial distribution in the impoundment, and a discussion of observations. The report will provide a narrative discussion of habitat use by aquatic fish and macroinvertebrates native to the study area. It is anticipated that data gathered during [Study No. 3.3.17](#) *Assess the Impacts of Project Operations of the Turners Falls Project and Northfield Mountain Project on Tributary and Backwater Area Access and Habitat* will also be used to develop the habitat map and discussion for this summary report.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The estimated cost for the study outlined in this plan is approximately \$30,000-\$45,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

It is anticipated that the aquatic mesohabitat assessment and mapping survey will be conducted in July – August 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.3.15 Assessment of Adult Sea Lamprey Spawning within the Turners Falls Project and Northfield Mountain Project Area***General Description of Proposed Study**

NOAA requested an assessment of adult sea lamprey spawning within the areas of the Turners Falls and Northfield Mountain Projects. FirstLight will conduct a field study to assess adult sea lamprey spawning within those areas during the late spring or early summer of 2014, but is proposing to substitute the methods described below in lieu of the telemetry methods suggested by NOAA.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to determine the impacts that operations of the Turners Falls Project and Northfield Mountain Project may have on sea lamprey spawning activity. Specific objectives of the study are to:

- Identify areas within the Project area where suitable spawning habitat may exist for adult sea lamprey.
- Conduct spawning surveys to confirm use of areas identified as containing suitable spawning habitat.
- Describe spawning mound characteristics, including location, size, substrate, water depth, and velocity.
- Determine if operations of the Turners Falls Project and Northfield Mountain Project are adversely affecting spawning areas (*i.e.*, if flow alterations are causing dewatering and scouring of lamprey spawning area).

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

Sea lamprey are a federal trust resource, and as such, NOAA Fisheries is charged with protecting the species and reducing threats to maintain its population. According to NOAA Fisheries, sea lamprey within the Connecticut River drainage are one of New Hampshire's and Vermont's Species of Greatest Conservation Need (SGCN). As outlined in Vermont's Wildlife Action Plan, research and monitoring needs for SGCN include monitoring and assessing populations and habitats for current conditions and future changes, and identifying and monitoring problems for species and their habitats.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Sea lamprey are an anadromous species known to spawn in the Connecticut River within the Turners Falls and Northfield Mountain Project Areas. They use mainstem and accessible tributary habitat consisting of gravel and cobble substrate in areas with flowing water in which they construct nests during spawning ([NOAA, 2013](#)). Sea lamprey pairs or groups (multiple fish may form an aggregate nest) can be observed building nests (or recently completed nests can be observed) in late-June ([Hartel et al., 2002](#); [NOAA, 2013](#)). Lamprey spawning has been observed from the Sunderland Route 116 bridge upstream to the base of the Cabot Station in shallow water habitats where preferred substrate occurs and where water velocities are increased due to a riverine physical characteristics (*e.g.*, shifts in depth contours, channel meanders, or islands) ([NOAA, 2013](#)). According to NOAA, the Connecticut River Coordinator (K. Sprankle, USFWS) has observed sea lamprey spawning in the Connecticut River mainstem upstream of the Turners Falls Dam within close proximity of the Vernon Dam (suitable habitat adjacent to Stebbins

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Island, both sides of island) ([NOAA, 2013](#)). Sea lamprey are also known to utilize lower reaches of tributaries, such as the Ashuelot River, Hinsdale, New Hampshire and mainstem gravel bar and shallow water habitats within the Turners Falls Impoundment (*e.g.*, Massachusetts State Line) ([NOAA, 2013](#)).

In 2012, 14,089 sea lamprey were passed upstream of Holyoke Dam, whereas 4,503 were passed at Turners Falls Dam. To date, no studies have been conducted that identify sea lamprey spawning habitat and/or activity or the effects of operations of the Turners Falls Project and the Northfield Mountain Project on spawning ([NOAA, 2013](#)).

FirstLight conducted studies in the late spring and summer of 2012 to examine habitat conditions downstream of Turners Falls Dam, including substrate composition. Habitat mapping indicated there is limited gravel-riffle spawning habitat in the mainstem downstream of Cabot Station or within the bypassed reach below Turners Falls Dam ([FirstLight, 2012](#)).

Project Nexus (18 CFR § 5.11(d)(4))

Operations of the Turners Falls and Northfield Mountain Projects have the potential to affect sea lamprey spawning activity, spawning habitat, and spawning success. If adult sea lamprey are actively spawning in the project area, it is important to assess whether Project operations are having any adverse effects (*i.e.*, dewatering and scouring) to these spawning activities, their nests, and spawning habitats.

The investigation area includes the following:

- Suitable gravel or cobble riffle habitat within the Connecticut River mainstem from Cabot Station downstream to Sunderland Bridge.
- Suitable gravel or cobble riffle habitat the Turners Falls bypassed reach (Connecticut River mainstem).
- Suitable gravel or cobble riffle habitat within the riverine portion of the upper Turners Falls Impoundment that is subjected to flow or elevational regulation resulting from project operations. Specifically, surveyors will focus in on the following two areas:
 - a. The Connecticut River mainstem within close proximity of the Vernon Dam (habitat adjacent to Stebbins Island, both sides of island).
 - b. Mainstem gravel bar and shallow water habitats within the Turners Falls Impoundment (*e.g.*, at or near the Massachusetts State Line).
- Suitable gravel or cobble riffle habitat within tributary confluence areas that are or may be affected by the current operational protocols, including:
 - a. The Deerfield River confluence with the Connecticut River.
 - b. The Millers River confluence with the Connecticut River.
 - c. The Ashuelot River confluence with the Connecticut River.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Field Data Collection**

Assessment of Sea Lamprey Spawning Activity and Habitat – Because sea lamprey nests and spawning pairs are generally readily observable (S. Coghlan, Assistant Professor of Freshwater Fisheries Ecology, University of Maine, personal communication, March 15, 2013) spawning activity will be determined via wading or boating surveys within the investigation area. Given sea lamprey life history and spawning patterns, it is anticipated that spawning ground surveys will be performed in late May or June, depending on water temperature and river flow. Surveyors will:

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Delineate areas of suitable habitat for lamprey (shallow, gravel or cobble riffles) with a sub-meter accuracy GPS.
- Physically locate and enumerate active or inactive nests.²¹
- Physically locate actively spawning lamprey.
- Photo document, geo-reference, and physically mark (with fluorescent marker or other relocatable marking device) active and inactive nests.
- Collect habitat data at representative nest sites including:
 - Nest dimensions (length/width), along with measurements of depth and velocity at the upstream end, top of mound, and bottom of pit.
 - Substrate classification.
 - Water temperature.

Once nests and spawning habitat are located and delineated, surveyors will return to a sub-sample of at least 30 randomly distributed individual nests (if available) throughout the investigation area during low water level conditions following a high-flow operational event to assess the effects on spawning habitat and nests. To ensure adequate spatial coverage and the evaluation of lamprey nests in multiple locations, the subsample will be divided among different large-scale location classifications (*i.e.* Turners Falls Impoundment; Bypass Reach; Downstream Corridor, *etc.*), with a goal of subsampling at least 10 nests in each determined location. At these stations, surveyors will:

- Photo document active and inactive nests during low water level conditions.
- Collect habitat data during low water level conditions to document changes resulting from Project operations, including:
 - Number of nests dewatered, partially or wholly.
 - Nest dimensions (length/width), along with measurements of depth and velocity at the upstream end, top of mound, and bottom of pit.
 - Water temperature.
- Delineate remaining wetted areas of suitable habitat (*i.e.*, spawning beds) for lamprey (shallow, gravel or cobble riffles) with a sub-meter accuracy GPS during low water level conditions for determinations of areal loss of habitat.

²¹ For the reach of the mainstem Connecticut River downstream of Cabot Station and below Vernon Dam, this will include using existing habitat data collected by FirstLight in 2012 or information related to known spawning sites to identify suitable habitat in advance of field surveys.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Data Analysis

All field data will be compiled, entered into a database, assured for quality, and archived. Tabular and graphic summaries of sea lamprey abundance and a map of the spatial distribution of suitable habitat will be developed.

Task 3: Report

A report will be prepared describing monitoring methods and results. The report will also include an assessment of impacts due to Project operations and whether changes to operational regimes could reduce potential adverse impacts to sea lamprey spawning and spawning habitat.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Turners Falls Project and Northfield Mountain Project on sea lamprey spawning in the investigation area. The estimated cost for this one-year study is approximately \$30,000 to \$45,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May14-15, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

FirstLight anticipates that this study will be conducted in late May or June of 2014, depending on water temperature and river flow conditions, which corresponds with sea lamprey spawning timeframes in the Connecticut River.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*3.3.16 Habitat Assessment, Surveys, and Modeling of Suitable Habitat for State-listed Mussel Species in the CT River below Cabot Station***General Description of Proposed Study**

MADFW requested a study investigating the effects of flow regime on state-listed freshwater mussels, or potential habitat, downstream from the Turners Falls Dam. Although the geographic scope of such a study was not defined in the MADFW study request, FirstLight defines the study area as the 13-mile reach between Cabot Station and the Route 116 Bridge in Sunderland. A two-phase approach is proposed for this study. In Phase 1, the study area will be surveyed for state-listed mussels using approved survey protocols; biologists will characterize populations of state-listed and co-occurring common mussel species, describe habitat conditions, and map/analyze habitat for any state-listed mussel species found in the study area. Phase 2 will focus on more detailed habitat measurements in areas where state-listed mussel species are found, and combine these data with hydraulic modeling and IFIM studies (described under separate study plans) to assess potential effects of the current flow regime on state-listed mussel populations or their habitat.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

This study has two objectives that can be accomplished in two phases:

- Phase 1: Delineate, through field surveys, populations of state-listed mussels downstream from Cabot Station and employ methods to characterize the distribution, abundance, demographics, and habitat use of these populations. Even if state-listed mussel species are not detected, surveys will identify and map potential habitat for state-listed species based on habitat preference of each species.
- Phase 2: Collect more detailed data on mussels and habitat parameters in areas where state-listed species are found, and combine these data with the independent hydraulic model and IFIM studies, to evaluate the effects of existing and potential flow regimes on state-listed mussel species.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The Massachusetts Natural Heritage & Endangered Species Program (NHESP), part of the MADFW, is charged with ensuring the conservation and protection of species listed under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) as Endangered, Threatened, or of Special Concern. The resource management goals identified by the NHESP/MADFW are to:

- Ensure that PME measures are commensurate with Project effects and meet MESA requirements.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations.

The MADFW study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, PME measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Species Composition: In 2011, a freshwater mussel survey was conducted in the Turners Falls Impoundment, bypass reach, and canal as a baseline study in anticipation of the FERC relicensing process. State-listed mussel species were not detected in any of these areas ([Biodrawversity, 2012](#)). Also in 2011, a freshwater mussel survey was conducted upstream and downstream of the Vernon Hydroelectric Project as part of the planning for TransCanada's FERC relicensing process, and no state-listed mussel species were found during that study ([Biodrawversity & LBG, 2012](#)). As part of the requirements of the FERC license for the Holyoke Dam, freshwater mussel studies have been conducted at four-year intervals in that project area, which includes the area from Dry Brook (Sunderland) to the Holyoke Dam, plus the bypass reach and power canals (this survey is scheduled to occur again in 2013). These studies, combined with surveys conducted for several riverbank stabilization or construction projects along this same reach, have resulted in a very good understanding of the distribution and habitat of common and state-listed mussel species in the Connecticut River from the Holyoke Dam to the Vernon Dam, minus a mostly unsurveyed 13-mile reach from the Route 116 Bridge in Sunderland to Cabot Station.

The yellow lampmussel (*Lampsilis cariosa*), listed as Endangered in Massachusetts, has been documented in the impoundment of the Holyoke Dam as far upstream as the Hadley Dike, with highest concentrations from Elwell Island (Northampton) downstream to Brunelle's Marina (South Hadley). The eastern pondmussel (*Ligumia nasuta*) has been found at only one location in the lower Holyoke Dam impoundment, and it occurs in several small tributaries. There is potential for either of these species to occur in the Connecticut River in the unsurveyed 13-mile reach downstream from Cabot Station. In addition, there is a historic record (~1978) of dwarf wedgemussel (*Alasmidonta heterodon*) in the Connecticut River from Sunderland, and it is possible that this species still persists in this reach. This is a federally endangered species, with the closest known populations in the Fort River (Amherst, MA), Mill River (Hatfield, MA), Ashuelot River (Swanzey, NH), and in the Connecticut River in the impoundment of the Bellows Falls Dam in New Hampshire and Vermont.

Impact of Flow Regime: The impacts of current flow regime on mussels downstream from the Turners Falls Dam are not well understood. There are significant within-day flow fluctuations downstream from the Turners Falls Dam. These changes in water elevations and flow dynamics have the potential to adversely affect state-listed mussels, their habitats, and their long-term viability in the Connecticut River. Species most vulnerable would be those that have an affinity for nearshore habitats, or other shallow areas that are most likely to become dewatered or in shallow water (where they may be vulnerable to heat stress or predators) during periods of low flow. Effects are expected to be most acute in areas of the river with channel morphometry, bank slope, and substrate conditions that are both conducive to mussel colonization and that experience the greatest degree of change from flow minima to flow maxima. The IFIM and hydraulic models studies proposed for this project, combined with the mussel surveys and habitat assessments that will be completed specifically during the mussel study, will help to identify both the species and locations where flow regime effects are more likely to occur, and will help provide an overall assessment of these effects.

Project Nexus (18 CFR § 5.11(d)(4))

The timing, rate, and magnitude of releases from the Turners Falls Project may have adverse effects on rare mussel populations although the degree of these effects is unknown. In order to evaluate the potential impacts of the Project on the abundance and distribution of state-listed mussel species and their habitat, baseline information is needed.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Finalize study plan and attain collection permit**

Because the study is focusing on state-listed mussel species, FirstLight will work with NHESP to finalize the study plan and attain the necessary permit to handle/collect state-listed mussels. FirstLight will comply with the conditions and reporting requirements of the collection permit.

Task 2: Phase 1 Mussel Survey and Habitat Assessment

Surveyors will systematically search the open water riverine habitats downstream from Cabot Station, employing the following protocol:

- The survey will be conducted when appropriate water clarity and water depth conditions are present, between early June and late September.
- Surveys will be conducted using SCUBA in depths over three feet, and by snorkeling in shallower waters.
- At least one site per mile, with additional sites in complex areas (such as around islands) will be surveyed for a minimum of 1.0 person-hours of survey effort per site. Additional time will be spent surveying areas where state-listed species are found to characterize and delineate these populations.
- The Catch per Unit Effort (CPUE) method will be used to qualitatively assess mussel species abundance. Specifically, the number of individuals of each species encountered within a defined amount of time will be tallied, and the CPUE values will be calculated and compared.
- Standard morphometric data (e.g., species, size, shell injury/erosion etc.) and site data (i.e., location, extent, elevation, and age class structure) will be collected. All state-listed mussel species encountered, and the first 50 individuals of common species, will be measured (mm) to enable assessment of size distribution and recruitment.
- For each state-listed mussel that is encountered, the following data will be recorded: precise location, water depth, substrate, presence/abundance of aquatic plants, presence/abundance of woody debris, and flow velocity.
- Representative digital photographs of each state-listed species will be taken at each site to document and confirm the identity. Photos showing the lateral view and/or in situ siphoning will be included.
- Representative samples of spent shells (if encountered) will be collected for each state-listed species; these will be sent to the Division for documentation.
- All mussels removed from the substrate will be replaced to the same area and carefully re-bedded into the sediment in their original orientation; anteriorly into the substrate, posterior end up.
- At all survey sites, biologists will record key instream habitat parameters such as water depth, flow velocity, major substrate types, aquatic plant species/abundance, abundance of woody debris, bank condition, and representative photographs.
- This general habitat assessment will provide habitat descriptions and maps to adequately describe the relative amount, distribution, and quality of suitable habitat for the state-listed freshwater mussels in areas influenced by the Turners Falls Project.

Task 3: Phase 2 Habitat Assessment and Mussel Survey

The Phase 2 habitat assessment and possible additional mussel surveys (e.g., quantitative surveys) will only be conducted at sites where state-listed mussel species are found. Given the potential to find either state-endangered or federally endangered mussel species, we think it is prudent to only outline a Phase 2

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

approach and commit to working with MADFW or USFWS to refine this approach listed below depending on Phase 1 results.

- Additional habitat data will be collected to support the IFIM study. Specifically, depth, velocity, and substrate profile(s) will be recorded at one or more cross-channel transects; the number of transects will depend on the size of the mussel bed and habitat complexity at a site.
- Both the boundaries of mussel beds and the wetted area will be delineated using GPS.
- If state-listed mussel densities are high enough, quantitative sampling (using quadrats or transects) will be employed to provide a more accurate assessment of density and population size at that location.

Task 4: Effects of Flow Regime on State-listed Mussels

The IFIM and hydraulic model studies proposed for this project, combined with the mussel surveys and habitat assessments that will be completed specifically during the mussel study, will help to identify where Project effects are more likely to occur, which species are more susceptible, and will help provide an overall assessment of these effects.

If state-listed mussels are detected and the Phase 2 mussel survey is completed, the IFIM and hydraulic models will be supplemented with the detailed habitat data collected at the sites where state-listed mussels are found, resulting in a more comprehensive assessment of the effects of flow regime on state-listed mussels.

Task 5: Report

A report will be prepared describing the survey and modeling methods and results. A tentative table of contents follows:

- Introduction
- Study Area
- Methods
 - Mussel Surveys
 - Habitat Assessment
 - Hydraulic Model and IFIM
- Results
 - Mussel Surveys
 - Habitat Assessment
 - Effects of Flow Regime
- Discussion
- Conclusions

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The methods and analyses proposed are consistent with other studies of this nature. The estimated cost for this study will depend, in part, on whether state-listed mussel species are found and the amount of mussel/habitat data that must be collected where state-listed mussels are found. Overall costs may range \$15,000 - \$60,000 (not including the hydraulic model and IFIM completed as a separate study). The cost for the Phase 1 mussel survey and habitat characterization would comprise the low end of that range; higher costs would likely only result from the discovery of state-listed mussels and the necessity of a Phase 2 mussel survey.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

Field work for the Phase 1 mussel survey is planned to occur in 2013, if possible, in advance of the instream flow study proposed in [Section 3.3.1](#). Completing the Phase 1 survey early in 2013 will help to determine if and where the Phase 2 mussel surveys are needed, and help inform the instream flow study. The remainder of any necessary work will occur in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*3.3.17 Assess the Impacts of Project Operations of the Turners Falls Project and Northfield Mountain Project on Tributary and Backwater Area Access and Habitat***General Description of Proposed Study**

The NHFGD, Town of Gill, MADFW, CRWC, VTDEC, TU and USFWS requested a study to determine if water level fluctuations due to Project operations result in a barrier(s) to fish movement in and out of tributaries and backwaters to the impoundments and riverine reaches below the dams. Additionally, the stakeholders requested an assessment of the impacts of water level fluctuations due to Project operations on water levels, available fish habitat and water quality in the tributaries and backwaters of the impoundment and riverine reaches below the dams. It is anticipated that this study will provide data that may be used to determine the adequacy of existing downstream minimum flow requirements.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goals of this study are to determine if water level fluctuations from the Turners Falls and Northfield Mountain Projects result in reductions of available aquatic habitat due to movement barriers and/or habitat alterations. Results from this study will be useful for developing mitigation measures and to determine the adequacy of existing downstream minimum flow requirements. Specific objectives of the study are to:

1. Identify potential barriers or constrictions of fish access to tributaries and backwater areas resulting from water level fluctuations.
2. Measure changes to available habitat, and water quality in backwater areas and tributaries resulting from water level fluctuations.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals identified by the commenting agencies are:

- Protect, enhance, or restore diverse high quality habitat necessary to sustain healthy aquatic and riparian plant and animal communities.
- Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize the potential negative effects of project operation on water quality and aquatic habitat, and mitigate for loss or degradation.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Major tributaries to the Turners Fall Impoundment include the Ashuelot River in New Hampshire, which drains 420 mi² from the east and enters the Connecticut River just below Vernon Dam, and the Millers River, which drains 392 mi² from the east and enters downstream of the Northfield Mountain tailrace. Smaller named streams entering the Turners Falls Impoundment, from upstream to downstream, include Newton Brook, Pauchaug Brook, Bottom Brook, Mill Brook, Mallory Brook, Millers Brook, Bennett Brook, Merriam Brook, Otter Run, Ashuela Brook, Dry Brook, Pine Meadow Brook, and Fourmile Brook.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

For the downstream reach from the base of the dam to the Route 116 bridge, major tributaries potentially impacted by Project operations include the Fall River, Deerfield River, Sawmill River, and Gunn Brook.

Limited information related to the potential impacts of the Turners Falls Project and Northfield Mountain Project operations on tributary/backwater access and habitats is available; therefore, the study is being completed to establish baseline conditions and assess the potential effects of existing or proposed operations. Given that the major tributaries to the Connecticut River in the project area (*i.e.*, Deerfield River, Miller River, and Ashuelot River) are large, regulated, and gauged river systems with ample catchment size, it is assumed that access to these major systems is afforded during all operational phases of the Turners Falls Project and Northfield Mountain Project. Therefore, the study will focus on smaller tributary systems that may not have enough river flow to maintain connectivity during drawdown periods.

Project Nexus (18 CFR § 5.11(d)(4))

Operation of the Turners Falls Project and Northfield Mountain Project may directly impact tributary/backwater and aquatic habitat access through the use of water for hydropower generation.

The investigation area includes the following smaller named streams entering the Turners Falls Impoundment, from upstream to downstream ([Figure 3.3.17-1](#))²² as well as significant backwatered areas within the Turners Falls impoundment:

- Newton Brook
- Pauchaug Brook
- Bottom Brook
- Mill Brook
- Mallory Brook
- Millers Brook
- Bennett Brook
- Merriam Brook
- Otter Run
- Ashuela Brook
- Dry Brook
- Pine Meadow Brook
- Fourmile Brook
- Backwater habitat encountered during survey work.

Investigation areas downstream of Turners Falls Dam will include the Fall River, Deerfield River, Sawmill River, and Gunn Brook (*see* [Figure 3.3.17-2](#)).

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

Common tools to evaluate water level impacts may be used including: bathymetric mapping; habitat measurements (*e.g.*, substrate, depth and velocity), and water quality information (*e.g.*, dissolved oxygen, temperature, turbidity, and pH). Other methods (river bed surveys, visual inspections, GIS/GPS mapping, and hydraulic/habitat modeling) will also be utilized. The study area for tributary and backwater sampling will include 13 smaller named tributaries along with other significant backwater habitat encountered

²² Assumes all of these tributaries are locatable.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

during the surveys. All field work described below would be performed once during the spring, summer, and fall of the first study year.

Task 1: Field Data Collection

For the purpose of this study, low water level conditions will be considered as 176.0 feet msl (or as close as is practical at the time of the study) in the Turners Falls Impoundment, and at a gage height of ≤ 8 feet at Montague for river reaches below the Turners Falls Dam.

Tributaries – Surveyors will locate individual tributary confluence areas within the Turners Falls Impoundment and the downstream reach to the Route 116 Bridge by boat or vehicle/foot during full-pond conditions or high water level conditions downstream. At each tributary site, surveyors will perform the following:

7. Photo document the tributary confluence area.
8. Delineate the perimeter of the inundated tributary confluence area with a sub-meter accuracy GPS. Aerial imagery may also be used to delineate tributary confluence areas.
9. Collect spot measurements of water temperature, dissolved oxygen, turbidity, and pH at one location within the inundated tributary confluence area. For comparison, measurements will also be taken at one location in the Connecticut River near the confluence area and in a free-flowing riverine reach immediately above the elevation affected by water level fluctuations.

Surveyors will then revisit tributary confluence areas during lower water level conditions to determine if stream intermittency or constrictions occur as a result of Project operations that would restrict fish movements into free-flowing riverine reaches. At each tributary site, surveyors will perform the following:

- 1) Photo document the tributary confluence area and any stream channel features (*e.g.*, barriers) that may restrict fish movements. Assessment and identification of these constriction points will be based on the best professional judgment of the biological staff employed to do the work. Generally, stream features with water depths less than 4-inches in the thalweg area will be considered as potential constrictions to fish movements.²³
- 2) Delineate the perimeter of the dewatered tributary confluence areas with a sub-meter accuracy GPS. Aerial imagery may also be used to delineate tributary confluence areas. Critical transects will also be GPS-located for future reference.
- 3) Characterize and map exposed aquatic habitats in the tributary confluence area.
- 4) If barriers to fish movement are observed:
 - Record and photo document their location.
 - Perform a longitudinal bathymetric/topographic thalweg²⁴ survey of the dewatered confluence area, with stream bed elevations relative to low water level elevation.
 - Perform a cross-sectional profile of stream channel features that may restrict fish movements.

²³ Given that these small tributaries are likely only used by resident riverine fish and perhaps sea lamprey, water depths greater than 4-inches will be considered adequate for upstream or downstream movements of fish.

²⁴ Point of lowest elevation.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Collect water depth, velocity, and substrate data at longitudinal and cross-section survey points.
- 5) Collect spot measurements of water temperature, dissolved oxygen, turbidity, and pH within the riverine portion of the tributary. For comparison, measurements will be taken in three areas (within the Connecticut River near the mouth of the tributary confluence, within the affected portion of the tributary, and upstream of the influence of the normal water level fluctuations).
- 6) Photo document and delineate areas subject to fish stranding (*e.g.*, standing pools without or with little outflowing water to allow for volitional fish movements to deeper waters).

Backwater Areas – For purposes of this study we have defined backwater habitat as areas with a notable increase in water surface elevation caused by a constriction or obstruction in flow, or off-channel habitats created as a result of floodplain (or other habitat features, *e.g.*, oxbow) development. Backwater habitats are characterized by slow currents, shallow water, and silty or vegetated substrates. To assess the effects of Project operations, surveyors will locate backwater areas during relatively high water levels. Surveyors will collect/perform the following at each backwater site at these conditions:

- 1) Photo document and GPS the location of individual backwaters.
- 2) As possible, delineate the perimeter of backwatered areas with a sub-meter accuracy GPS. Aerial imagery may also be used to delineate backwater habitat.
- 3) Collect spot measurements of water temperature, dissolved oxygen, turbidity, and pH within the backwater. For comparison, measurements will also be taken in the impoundment near the backwater area.

Surveyors will then revisit backwatered areas during low water level conditions to assess connectivity and habitat conditions. The following information will be collected:

- 1) Photo documentation of backwaters at low water level conditions.
- 2) Photo documentation and GPS mapping of areas subject to fish stranding (*e.g.*, standing pools without or with little outflowing water to allow for volitional fish movements to deeper waters).
- 3) If barriers to fish movement are observed:
 - Record and photo document their location,
 - Perform longitudinal bathymetric/topographic thalweg survey of backwater area, with bed elevations relative to low water level elevation.
 - Collect water depth, velocity, and substrate data at longitudinal and cross-section survey points.
- 4) Collect spot measurements of water temperature, dissolved oxygen, turbidity, and pH within the backwater. For comparison, measurements will also be taken in the Connecticut River near the backwater area.

Task 2: Evaluation of Fluctuation Range

If it is determined that the existing flow fluctuation range creates barriers to fish movements in tributaries and/or backwatered areas, or adversely affects aquatic habitat, FirstLight will perform modeling/GIS studies to evaluate if changes in water level fluctuation range would mitigate for any identified impacts. Modeling software (*i.e.*, HEC-RAS or River 2D or comparable) will be used to develop a GIS to demonstrate changes in tributary or backwater access (including resultant water depth and water velocity modeling) at identified barriers and habitat conditions.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 3: Data Analysis and Reporting

Data will be compiled and analyzed after each sampling effort. Data will be developed in tabular and graphic format for inclusion in draft and final report preparation.

The report will be submitted as part of the Initial Study Report as per the ILP process schedule.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

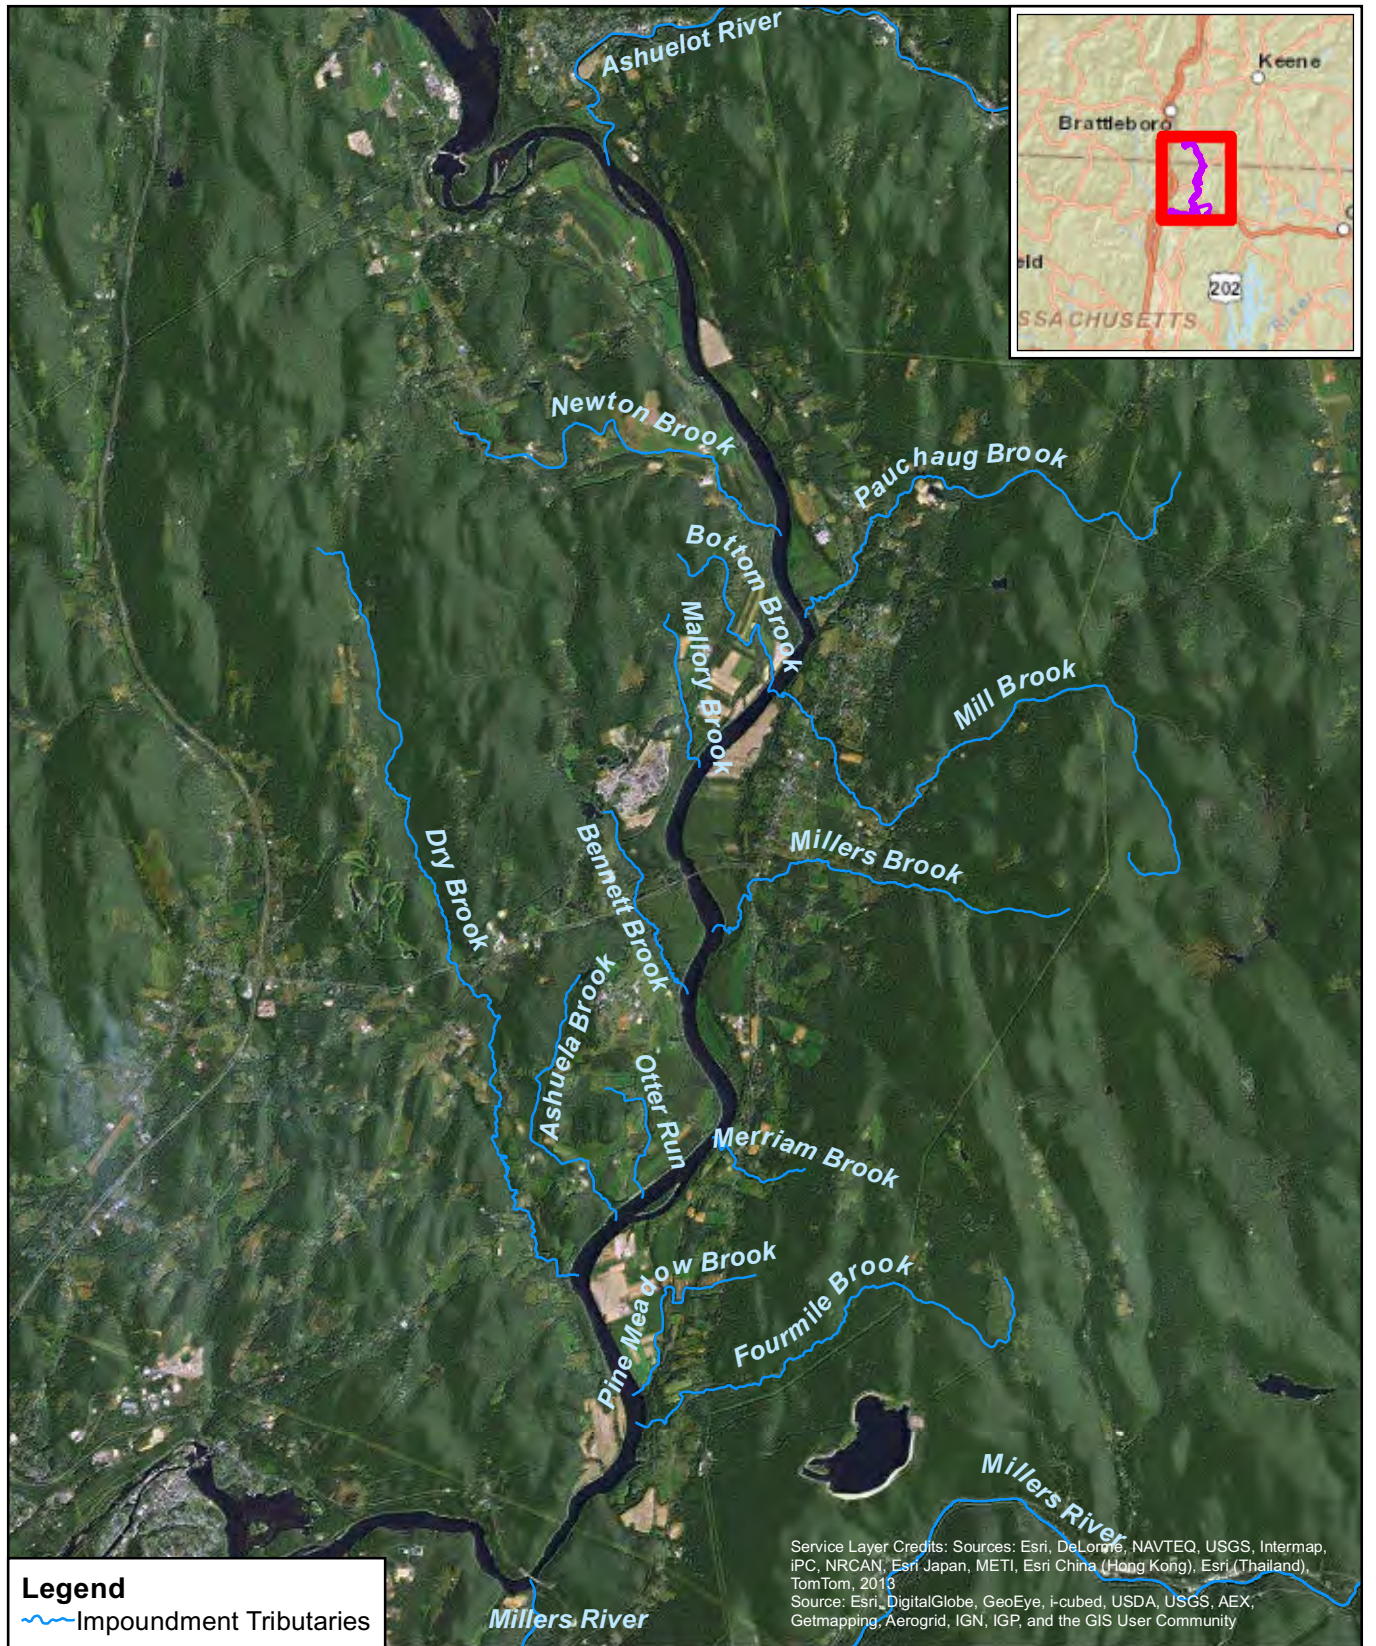

FirstLight believes the proposed level of effort is adequate to accurately assess the potential effects of the Turners Falls Project and Northfield Mountain Project on tributary and backwater access in the investigation area. The estimated cost for this one-year study is approximately \$30,000 to \$45,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

It is anticipated that this survey will be conducted in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

3.3.18 Impacts of the Turners Falls Canal Drawdown on Fish Migration and Aquatic Organisms**General Description of Proposed Study**

In the study request letter from the USFWS, a study to quantify the impacts of the annual Turners Falls Project canal drawdown on emigrating and resident fishes, freshwater mussels and mudpuppies in the canal was requested. Similar requests were also received from the MADFW, NHFGD, NOAA, CRWC, and TU. The stakeholder's indicate that the study request is intended to facilitate the collection of information necessary to conduct effect analyses and to develop reasonable and prudent conservation measures, along with PME measures.

Historically, FirstLight has conducted annual surveys of the canal during drawdown events. In 2011, a more extensive survey was conducted and documented in a memo report as explained below under the Existing Information discussion. FirstLight believes existing information is sufficient to qualitatively assess effects of the drawdown on emigrating and resident fish and aquatic organisms. Rather than conduct additional surveys at a level necessary to quantify effects, FirstLight instead proposes to conduct an assessment of potential measures to reduce adverse effects due to dewatering for the annual drawdown events in 2014.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to identify and evaluate potential measures to reduce adverse effects due to dewatering for the annual canal drawdown events. The objectives are to:

- Determine which mitigation measures are to be implemented.
- Design and implement mitigation measures.
- Survey fish and aquatic organism populations during canal drawdown after implementation of mitigation measures.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The CRASC developed *A Management Plan for American Shad in the Connecticut River Basin* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Maximize outmigrant survival for juvenile and spent adult shad.

The ASMFC Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, has the stated goal of “*Protect, enhance, and restore Atlantic coast migratory stocks and critical habitat of American shad in order to achieve levels of spawning stock biomass that are sustainable, can produce a harvestable surplus, and are robust enough to withstand unforeseen threats,*” and includes the following objectives:

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

2. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g. turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

The USFWS seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Turner Falls Project. General goals include the following:

1. Ensure that PME measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Turners Falls Project.

Specific to diadromous fishes, the USFWS goal is to minimize current and potential negative project operation effects on diadromous fishes, including juvenile shad, adult silver eels, and sea lamprey ammocetes.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Historically, FirstLight has observed stranding of juvenile American shad during annual drawdown events. In 2011, FirstLight's consultant and staff from Conte Lab conducted a more formal survey to include delineation of the canal into seven distinct zones. Each zone was visually surveyed for juvenile shad and other species, which were counted or estimated depending on numbers present. Any pool areas were documented with photos and represented on aerial photos. A summary report was developed and is provided in Appendix G of this PSP. While no shad were observed, probably because of a flood event prior to the drawdown, a variety of species were documented, including centrarchid and cyprinid species, sea lamprey, carp, perch, mussels, chain pickerel, and American eel. Numbers observed varied by zone and by species.

The 2011 survey effort largely qualitatively addressed stakeholder objectives to evaluate presence and abundance of species stranded during a typical canal drawdown. FirstLight believes that mapping and photo documentation of pool locations and locations of fish observations, as well as canal bed conditions during a drawdown event are sufficient to identify habitat types and assess how drawdown events may affect fish present in the canal and that a more detailed quantitative evaluation is not necessary.

Project Nexus (18 CFR § 5.11(d)(4))

Previous studies at Cabot Station have documented that juvenile American shad and American eel migrate through the project area during the canal drawdown period. During normal operations (where canal water level elevations are stable), downstream migrants are able to utilize the Cabot bypass facility; however, as the canal water level is drawn down, the bypass is no longer available, and the only routes of egress are through the turbines at Cabot Station and Station No. 1, unless the Cabot Station spill gates are utilized.

Once the canal has been drawn down, isolated shallow pools remain until the canal is refilled. During this period, fish (including lamprey ammocetes), amphibians, and benthic invertebrates are prone to desiccation, predation or other sources of mortality.

The annual canal drawdown was formerly conducted in July. In response to ISO-NE's request that FirstLight conduct the drawdown outside of the June through August period, FirstLight moved the

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

drawdown to September, which coincides with the part of the migration period for some diadromous species.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

The 2011 survey effort identified above (see Appendix G for summary report) largely addresses stakeholder objectives to evaluate the presence and abundance of species stranded during a typical canal drawdown event in a qualitative manner. FirstLight believes that mapping and photo documentation of pool locations and locations of fish observations, as well as canal bed conditions during a drawdown event are sufficient to identify habitat types and assess how drawdown events may affect fish present in the canal and does not necessitate a quantitative evaluation. Therefore, rather than conduct an additional field study in 2014, FirstLight proposes to fulfill the objectives of this study as follows.

Task 1: Identify and Assess Potential Measures

This task will be conducted in 2014 and consist of consulting with agencies and other stakeholders to identify and evaluate potential measures that may reduce adverse effects on fish in the canal during drawdown conditions. Potential measures may include, but not be limited to, assessment of drawdown timing or placement of temporary weirs or baffles in select areas of the canal to enlarge pools that remain during drawdown events or create additional pools to keep specific habitat areas wetted for the duration of the drawdown event. The Task 1 evaluation will compare the merits and drawbacks of each measure, as well as develop an order-of-magnitude cost estimate. Should FirstLight and stakeholders reach an agreement on the most appropriate measure(s) to evaluate in the field then engineering design will proceed in Task 2 with the goal of field-testing the selected measure(s) during the 2015 drawdown event.

Task 2: Design Selected Measure(s)

Upon agreement between FirstLight and stakeholders on the most appropriate measure(s) to reduce adverse effects on aquatic organisms during drawdown events, engineering design (if applicable) of the selected measure(s) will be developed for field-testing during the 2015 drawdown event.

Task 3: Field-test Selected Measure(s)

The measure(s) designed in Task 2 will be tested during the 2015 drawdown event to assess effectiveness in reducing impacts to aquatic organisms in the canal. Methodology of the assessment will be similar to previous aquatic organism assessment during canal drawdown. The measure of 'effectiveness' will be jointly determined through consultation with agencies and stakeholders during the evaluation of alternatives in Task 1. The results of field testing will be documented and provided to agencies and stakeholders for review.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes the proposed level of effort is adequate to assess potential measures to effectively reduce the impacts of the annual drawdown events on aquatic organisms present in the canal. The total estimated cost for the proposed study is approximately \$55,000 - \$75,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

FirstLight anticipates conducting Task 1, as noted above, in 2014 with the remaining study efforts occurring in 2015.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.3.19 Evaluate the Use of an Ultrasound Array to Facilitate Upstream Movement to Turners Falls Dam by Avoiding Cabot Station Tailrace***General Description of Proposed Study**

An evaluation of the use of an ultrasound array to facilitate upstream movement of American shad to Turners Falls Dam by avoiding Cabot Station Tailrace was requested by USFWS, NHFG and CRWC. For this scenario to be effective, adult shad attraction to the Cabot Station discharge would need to be addressed. This study will be performed in the second study season so as to not effect the results of the work conducted under [Study No. 3.3.2: Evaluate Upstream and Downstream Passage of Adult American Shad](#), and will attempt to determine if use of ultrasound technology would be an effective method to minimize attraction to the tailrace discharge while facilitating movement past the Cabot discharge and up to the spillway area.

The location of the proposed array would be in the area of the identified shortnose sturgeon spawning grounds. It would need to be operated during the sturgeon spawning season as the shad upstream migration and sturgeon spawning periods overlap.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to determine if use of ultrasound is an effective behavioral mechanism to create avoidance of the Cabot Station tailrace area by upstream migrating adult shad. If not attracted to the Cabot Station discharge, shad may proceed upstream and pass the Turners Falls Dam via the fishway at the dam.

The objective of the study would be to establish a high frequency sound (ultrasound) array across the entire Cabot Station tailrace and determine the effect of the ensonified field on upstream migrating radio-tagged shad moving past Cabot Station. This would be accomplished by monitoring the movements and passage of shad and the time shad spent in the tailrace area.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

In 1992, the Connecticut River Atlantic Salmon Commission (CRASC) developed a draft document titled: *A Management Plan for American Shad in the Connecticut River Basin*.

Management Objectives in the plan include the following:

Specific management objectives in the plan include the following: Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually; achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem; and maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, includes an objective to maximize the number of juvenile recruits emigrating from freshwater stock complexes.

Amendment 3 also includes the following recommendations for upstream passage:

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- American shad must be able to locate and enter the passage facility with little effort and without stress.
- Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
- Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

In spite of the extensive studies and many successes for some species of fish at some station intakes, as yet, there is no one behavioral barrier or deterrent that is effective with all species and lifestages of fish. Behavioral barriers are generally still considered experimental.

High frequency sound was used at the James A. Fitzpatrick power plant located on Lake Ontario, and was found to reduce impingement of alewife by more than 80 percent and its use was approved by the regulatory agencies. Similar avoidance by herring species was noted where sound was tested at hydroelectric sites.

American shad and alewife belong to the same family, Clupeids, and as such may react similar to high frequency sound. Information exists about adult shad avoidance of ultrasound. In field trials in the early 1980s to develop a guidance system for downstream-migrants in the First Level Canal of the Holyoke Canal System, adult shad avoided but were not well guided by an ultrasonic array. However, upstream migrants were guided well and even stopped entirely by the ensonified field (Kynard and Taylor, 1984). Creating an ensonified field caused adult shad to leave their preferred location in the river upstream of trashracks at Holyoke Dam as long as the sound system was on.

Blueback herring also avoided the ultrasound field and behaved similar to shad in the Holyoke Canal studies (Kynard and Taylor, 1984). Acoustic barriers have been used for blueback herring on the Savannah River (Richard B. Russell Dam) and Santee River (St. Stephen fish lift) in South Carolina and on the Mohawk River in New York (Crescent Project, FERC No. 4678; Vischer Ferry, FERC No. 4679). Evidence from many studies that attempted to produce behavioral avoidance by adult shad suggests that ultrasound is an effective stimuli (Carlson and Popper, 1997). Evidence suggests that shad and blueback herring may avoid the tailrace of Cabot Station if an ultrasound field was installed.

Project Nexus (18 CFR § 5.11(d)(4))

Studies to assess potential passage solutions are frequently conducted during relicensing proceedings. This study, coupled with the adult shad radio-telemetry study, can provide the information needed to select an approach to resolve upstream shad passage at the Turners Falls Project.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Ultrasound Deployment**

This study would establish a high frequency sound (ultrasound) array across the entire Cabot Station tailrace and determine the effect of the ensonified field on upstream migrating shad moving by Cabot Station by monitoring shad behavior. Telemetry methods like those proposed in Study Plan 3.3.2 will be utilized. FirstLight will consult with the agencies to determine a schedule to turn the array off and on.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Reporting

Data collected in Task 2 will be analyzed to determine if ensonification is a successful deterrent mechanism. A report will be prepared detailing methods, results, a discussion and conclusions.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The cost for the test would be \$55,000 to \$70,000. Costs will be related to rental, installation, and operation of the ultrasound system, analysis of data, and production of a final report. The study could utilize the same monitoring equipment as the adult shad radio telemetry study (although a few additional tracking stations may have to be installed in the Cabot Station tailrace).

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The study proposed herein will be conducted in the second study season, after the adult shad study described in [Section 3.3.2](#), *Evaluate Upstream and Downstream Passage of Adult American Shad*. American shad migrate up the river when water temperatures are generally between 12 and 20°C; spawning occurs from 14 to 23°C when river flow is generally declining from the spring peak with shad reaching Cabot Station in late April or early to mid- May. The ultrasonic array and shad monitoring equipment will be deployed, calibrated and tested in late March and early April, prior to the arrival of adult shad to the study area. Spent outmigrants travel downstream shortly after spawning. The exact timing of the out-migration will be dependent on many factors, most notably water temperature. The study is anticipated to conclude by mid-July.

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

3.4 Terrestrial Wildlife and Botanical Resources**3.4.1 *Baseline Study of Terrestrial Wildlife and Botanical Resources at the Turners Falls Impoundment, the Bypass Reach and below Cabot Station within the Project Boundary*****General Description of Proposed Study**

In its PAD, FirstLight proposed to conduct a study to obtain baseline information on terrestrial wildlife and botanical resources in the Turners Falls Impoundment, the Bypass Reach, and below Cabot Station within the Project boundary. The Town of Montague, MA requested that FirstLight complete a wildlife habitat assessment of the Turners Falls Bypass.

Note that terrestrial resources around the Northfield Mountain Project are being studied, as described in [Study No. 3.4.2](#).

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to characterize and describe the terrestrial wildlife and botanical resources that use representative upland habitats within the Project boundary. Specific objectives are:

- Survey and inventory overall existing upland wildlife habitats;
- Note the occurrence of wildlife sighting during the course of the surveys;
- Survey and inventory vegetation cover classes and land use;
- Survey and evaluate the presence of targeted RTE species or associated habitats;
- Survey and inventory the nature and extent of invasive and exotic vegetation species; and
- Assess the effects of current and future operations on terrestrial wildlife and botanical communities.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

This study plan will provide baseline information to agencies with jurisdiction over wildlife and botanical resources allowing them to address potential Project effects. Resource management goals relevant to terrestrial wildlife and botanical resources studies are described below.

Terrestrial wildlife resources are administered by the USFWS. The mission of the USFWS is to "conserve, protect and enhance fish, wildlife and plants and their habitats for the continuing benefit of the American people." In doing so, USFWS enforces wildlife laws, protects endangered species, manages migratory birds, and helps to restore important fisheries. They administer the ESA, designed to protect imperiled species from going extinct.

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program (NHESP) of the MADFW. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions and protection of wetlands and aquatic habitats of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The MADFW's resource goals and regulatory requirements are to:

- Ensure that protection mitigation and enhancement measures are commensurate with Project effects and meet MESA and the WPA requirements for the Project.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Conserve, protect, and enhance habitats for state-listed species that will be affected by Project operations.

Massachusetts Invasive Plant Advisory Group (MIPAG) maintains a list of invasive plant species in Massachusetts and provides criteria used in evaluating species. The NHESP management goal is to promote the conservation and protection of species that are not hunted, fished, trapped or commercially harvested in Massachusetts. The NHESP highest priority is protecting the state listed RTE species. The overall goal of the program is the protection of the state's wide range of native biological diversity.

The conservation goals of the VDFW are to:

- Maintain or increase populations of rare, threatened and endangered species in the area of interests;
- Maintain, restore, provide long-term stewardship of, or conserve habitats and natural communities that support rare, threatened and endangered species.

NHFG primary management goals relative to terrestrial and wildlife resources are to restore and maintain critical habitats and populations of the state's species of conservation and management concern.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

The PAD provides a list of plant and wildlife species, as well as dominant vegetative communities in the Project area, but does not provide any site-specific information on the known occurrences of species within the upland habitats of the Project. Additional site-specific data are needed to meet the goal of evaluating Project effects. Studies will supplement existing information regarding vegetation mapping, invasive plants, and presence of RTE species or associated habitat.

Project Nexus (18 CFR § 5.11(d)(4))

The Turners Falls Project and Northfield Mountain Project provide habitat for a variety of wildlife and botanical species. Water levels fluctuations have the potential to affect habitat for a variety of life stages of terrestrial resources. An understanding of the terrestrial resources in the project area would provide information on the type and quantity of habitat potentially affected by Project operations.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

A field survey of the shoreline will be conducted within the Turners Falls Impoundment, in the Bypass Reach, and below Cabot Station to the downstream extent of the Project boundary to document the type and distribution of wildlife habitats, including vegetation communities and plant species, present in the project area. A field survey of wildlife species will be conducted concurrently with other botanical and wetland studies ([StudyNo. 3.5.1](#)). Surveys will be conducted by biologists visually assessing habitats along and above the shoreline from boat and/or walking on FirstLight and public lands during the growing season when vegetation is most conspicuous and readily identifiable. The presence of any RTE species or habitats will also be noted. Any direct observations of RTE species documented in the Project area will be processed in accordance with applicable State and Federal procedures and all data and records will be available immediately to appropriate organizations (FirstLight, USFWS, MADFW).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 1: Literature Review

The initial step prior to the field reconnaissance surveys will include reviewing existing information and data to identify areas of representative communities and potentially suitable habitat for protected species of interest. Using GIS and other available sources of information, a preliminary base map will be produced to assist field surveys. To refine the vegetation and habitat mapping for the study area, the following tasks will be performed:

- Acquire and compile existing GIS vegetation cover type layers from available resources;
- Examine any visible vegetation boundaries in aerial photos or other imagery to fix or update type polygon boundaries, based on field observations;
- Produce a final vegetation type map that displays vegetation type polygon boundaries, the study area, and specific Project components; and
- Use the vegetation type map to produce a table of vegetation types and calculate the percent acres of each vegetation type present in the study area in general, in areas potentially affected by the Project, and indirectly affected key wildlife habitats.

Task 2: Field Surveys

Field surveys will be conducted to document wildlife habitat and occurrence, vegetative cover types and invasive plant species in the Project area, as described further below.

Wildlife and Habitat Type Mapping

The primary objective of wildlife surveys for the Project is to provide information on the distribution and abundance of wildlife habitats. General habitat field notes will record dominant vegetation cover classes and land use; unique or unusual habitat types; observations of avian, reptile, amphibian, and mammal species; and locations of invasive plant species. Wildlife surveys will be conducted through the use of visual encounter surveys concurrent with the habitat type verification mapping. Transect lines parallel to the shoreline will be placed randomly or at least objectively with respect to representative habitats present along the shoreline. The total number of transects will be determined after an initial site reconnaissance. The observer will walk a transect at a pace of approximately five minutes per 50 meters, for a total search time of approximately two hours. During these searches, an observer will survey the area to either side of the transect, looking for targeted species or indirect signs (i.e., tracks, scat, den areas, nests, etc.) Each transect will be surveyed only once per season, however, qualitative data from other similar surveys efforts will also be noted and included in the overall wildlife census list.

More intensive casual searches will be performed for individual species in appropriate areas where suitable habitat is observed (such as searching for amphibians under logs). Other supplemental techniques, such as broadcast or listening surveys will be used to improve the odds of detecting some more elusive avian and amphibian species. The locations of significant sightings or observations will be documented through the use of GPS and geo-referenced photographs and then entered into the GIS data base. Data collected will be compiled into a Project area species list.

Vegetation Cover Type Mapping

The overall design of the vegetative mapping is to identify all vascular botanical species within the Study Area while focusing on the targeted listed species and other RTE plant species. Botanical assessments will be completed to determine the species composition, structure, and distribution of vegetative communities. The types of data that will be collected include percent cover and dominant species within

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

the herbaceous, shrub, and tree stratum along with the general distribution and juxtaposition of vegetative communities. Timed-meander surveys will be conducted in representative habitat types encountered within the Study Area. The meander survey will involve walking a wandering path through each habitat and recording species present until a period of time (typically for approximately ten minutes) passes where no new species were added to the vegetation list. Surveyors will compile a list of all plants found within each respective habitat, and will maintain an overall census list of all plant species identified within the Project Area. Plants will be identified to the species level if possible, or at a minimum, if the plant is outside its phenological peak, the plant will be identified to the genus level if species identification is not possible. If positive identification cannot be completed in the field, a voucher sample can be collected, pressed, and preserved for further identification when appropriate.

Prior to the 2014 field survey, biologists will obtain the necessary collecting permit for any voucher samples that may need to be collected from the State Botanist at the Massachusetts NHESP. Biologists will also coordinate with VDFW and NHFG RTE programs if similar collection permits are required for voucher samples prior to any field studies. Other general information that will be gathered during meander surveys will include general health of communities and site quality conditions. Vegetation communities will be classified using the NHESP Classification of the Natural Communities of Massachusetts ([Swain & Kersey, 2011](#)).

Multiple sample vegetation plots will also be established to collect quantitative information to characterize the different habitats and provide species composition of habitat types. Vegetation plot locations will be selected using NHESP guidelines and protocols. A NHESP Quantitative Community Characterization Form (NHESP Form 3) will be completed for representative habitats to document the results of each plot location. Geo-referenced photographs will also be taken to document site conditions at the time of the survey.

Invasive Plant Survey

The MIPAG maintains a list of invasive plant species in Massachusetts and provides criteria used in evaluating species. The MIPAG species list of invasive plants will be utilized to identify targeted invasive species when conducting botanical meander surveys. Surveyors will use methods adapted from the USFS Invasive Species Program, Invasive Species Inventory and Mapping Data Recording Protocols. These adapted methods focus on presence, location, extent, abundance and other site characteristics to provide site infestation information.

To document an infested area, biologists will use GPS at sub-foot accuracy to delineate the boundary of the infestation as defined by the dominant canopy cover of the invasive plant. Areas containing only occasional invasive species will be characterized with a GPS center point and radius necessary to enclose the population will be used. For areas where invasive species are ubiquitous or impractical to map, surveyors will characterize the invasive species population using estimates of aerial coverage and percent of species present. All sampling areas containing invasive botanical species will be photo-documented with geo-referenced photos, and an Invasive Species Documentation Form will be completed.

Task 3: Data Analysis and Reporting

A draft and final technical report will be prepared for this study. The results of this study will provide both quantitative and qualitative information that will be important in defining existing conditions, as well as providing any information on potential project impacts. The report will contain all supporting correspondence among licensing participants. The draft report will be revised to address final comments by licensing participants.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Level of Effort and Cost (18 CFR § 5.11(d)(6))

This study would likely take one study season to complete. The estimated budget for the study ranges from approximately \$40,000 to \$60,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The Inventory will be conducted as follows:

- January – March 2014: Reviewing existing information and data
- April - August 2014: Conduct field reconnaissance surveys
- September - December 2014: Prepare data and report

Literature Cited

Swain, P.C., & Kersey, J.B. (2011). Classification of the Natural Communities of Massachusetts: Draft. Retrieved from http://www.mass.gov/dfwele/dfw/nhesp/natural_communities/natural_community_classification.htm. Accessed August 23, 2011.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.4.2 Effects of Northfield Mountain Project-related Land Management Practices and Recreation Use on Terrestrial Habitats***General Description of Proposed Study**

FERC requested FirstLight to complete a study to provide baseline information on wildlife and botanical habitats occurring in the Northfield Mountain Project area, and study the effects of Northfield Mountain Project-related land management practices and recreation use on terrestrial habitats.

FirstLight is proposing a study to collect baseline information, which will inform an assessment of Project-related land management practices and recreational use impacts on terrestrial resources on Project lands at the Northfield Mountain Project.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of this study is to gather information necessary to understand the potential effects of land management practices and recreational use on wildlife and botanical resources within the Northfield Mountain Project area. The objectives of this study are to provide supporting information which will provide the basis for an assessment of the potential resource impacts of the Project that were identified during development of the PAD and FERC scoping for the License Application, as follows:

- Identify and describe FirstLight's Project-related land management practices (including the maintenance of Project-related recreation areas) occurring in the Northfield Mountain Project boundary;
- Provide information pertinent to describe existing wildlife and botanical habitats occurring in the Northfield Mountain Project area;
- Determine if Project-related land management and maintenance practices and the use of Project-related recreation areas has the potential to facilitate the growth and spread of invasive plant species; and
- Provide information to identify if Project-related land management and maintenance practices and the use of Project-related recreation areas may affect existing wildlife and botanical resources (e.g., clearing of vegetation).

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

This study plan will provide baseline information to agencies with jurisdiction over wildlife and botanical resources allowing them to address potential Project-related effects. The Connecticut River watershed support a diverse assemblage of plant and wildlife communities that provide various public opportunities, such as bird watching, hiking, and hunting. Consideration of the effects of Project operations, maintenance, land management, and recreational use on these resources is relevant to the Commission's public interest determination.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

The PAD provides baseline information pertaining to the effects of project operation, maintenance, land management, and recreation use on wildlife and botanical habitats and the location of invasive plant species within the Northfield Mountain Project area. FirstLight is proposing to conduct wildlife and botanical studies for the Turner Falls Project as outlined in [Study No. 3.4.1](#) and [Study No. 3.5.1](#); however, those studies only address the Turner Falls Impoundment (lower reservoir for the Northfield Mountain Project) and downstream areas with a focus on assessing Project operations primarily associated with

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

water level fluctuations. Additional information on the location and abundance of invasive plant species and the impacts on wildlife and botanical resources as a result of project-related maintenance and land management practices in the Northfield Mountain Project area are needed to evaluate the Project's full effects on wildlife and botanical resources.

In 2006, FirstLight, formerly operating under the NE Hydro Generating Company name, contracted Tighe & Bond, Inc. to complete a botanical survey on Project lands where land management and recreational activities occurred. The areas surveyed included Bennett Meadow Wildlife Management Area, Barton Cove Campground and a Picnic Area on the Turners Falls Impoundment. The summary report describes the survey efforts that focused on the lower impoundment, which provides insight as to which species are within those areas surveyed and what could potentially be at other sites within the Northfield Mountain Project boundary. In the MADFW review letter dated April 25, 2007 from the MADFW to Tighe & Bond (NHESP Tracking Number: 06-19884), the MADFW indicated that the Northfield Mountain Recreational Trails are not located within Priority Habitat or Estimated Habitat and concluded that existing uses of the recreational facilities described in the Operation and Maintenance Plan would not require review under the MESA; however, select activities which are regulated by FERC licenses may require review by NHESP during the FERC review process.

FirstLight conducted a recreational facilities inventory at the Turners Falls Project and Northfield Mountain Project during two field visits in October 2011 and July 2012 (see [Study No. 3.6.2](#)). The purpose of the inventory was to identify the current formal recreational facilities associated with the Projects. This information was needed to prepare the recreation sections of the PAD. TRC developed a report (2012) of these facilities providing a summary of each formal recreational facility that was inventoried. This report will be used as baseline information as to what types of recreational use could potentially affect wildlife and botanical habitats at the Northfield Mountain Project.

Project Nexus (18 CFR § 5.11(d)(4))

The Northfield Mountain Project provides habitat for a variety of wildlife and botanical species. An understanding of the terrestrial resources in the Project area would provide information on the type and quantity and quality of habitat potentially affected by Project-related land management and maintenance practices and the use of recreational areas.

The Northfield Mountain Project has many recreational features (e.g., a trail system with over 26 miles of trails, observation area, picnic areas) that are inherently attractive. Public recreation sites can affect wildlife behavior (both attracting and displacing) and impact botanical resources (e.g., trampling and spreading invasive species). An analysis of the effects of the maintenance, land management practices, and use of these recreational features on wildlife and botanical resources would help form the basis for determining the Project's effect on these resources.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

For the purposes of this study, the Northfield Mountain Project area includes the lands around Project facilities (e.g., lands around the upper reservoir, parking areas, access roads) and recreational areas (e.g., picnic areas, trails, and hiking areas) on Northfield Mountain.

A field survey of wildlife and botanical species will be conducted concurrently with other field surveys where applicable. Wildlife and botanical resource assessments will be conducted on the terrestrial, wetland, riparian, and littoral areas of the Turners Falls Impoundment, bypass and downstream areas as described in [Study No. 3.4.1](#) and [Study No. 3.5.1](#). Surveys will be conducted by biologists during the 2014 growing season.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 1: Literature Review

A pre-survey review of existing information and data will be completed to identify areas of representative communities, land use classes, recreational areas and trails, invasive species and potentially suitable habitat for protected species of interest as identified in Section 4.7 of the PAD. Using GIS and other available sources of information, a preliminary field map will be produced to assist field surveys.

Prior to field investigations, researchers and biologists will review and screen the practices and locations of FirstLight Project-related land use management activities (e.g., areas routinely mowed, vegetation management areas, access roads) and recreational uses (e.g., trails, climbing areas, camping, skiing) at the Northfield Mountain Project.

Task 2: Wildlife and Habitat Type Mapping

The primary objective of wildlife surveys for the Northfield Mountain Project is to provide a general census and information on the distribution and abundance of wildlife habitats. General habitat field notes will record dominant vegetation cover classes; unique or unusual habitat types; and observations of avian, reptile, amphibian, and mammal species. Wildlife surveys will be conducted through the use of visual encounter surveys along transects. Transect lines will be placed randomly or at least objectively with respect to representative habitats, including representative Project-affected habitats (i.e., areas of vegetation management, recreational use areas). The total number of transects will be determined after an initial site reconnaissance in early spring. The observer will walk a transect at a pace of approximately five minutes per 50 meters, for a total search time of approximately two hours. During these searches, an observer will survey the area to either side of the transect, looking for targeted species or indirect signs (i.e., tracks, scat, den areas, nests, etc.). Each transect will be surveyed only once per season, however, qualitative data from other similar surveys efforts will also be noted and included in a overall wildlife census list. More intensive casual searches will be performed for individual species in appropriate areas where suitable habitat is observed (such as searching for amphibians under logs). Other supplemental techniques, such as broadcast or listening surveys will be used to improve the odds of detecting some more elusive avian and amphibian species. Field studies will be conducted on a seasonal basis in order to record species when they are most conspicuous. The locations of significant sightings or observations will be documented through the use of GPS and geo-referenced photographs and then entered into a GIS data base. Data collected will be compiled into a Project area species list.

Task 3: Vegetation Cover Type Mapping

Botanical assessments will be completed to determine the species composition, structure, and distribution of vegetative communities. The types of data that will be collected include percent cover and dominant species within the herbaceous, shrub, and tree strata along with the general distribution and juxtaposition of vegetative communities. Timed-meander surveys will involve walking a wandering path through each representative habitat type and recording species present until a period of time (usually 10 minutes) passes where no new species were added to the vegetation list. Surveyors will compile a list of all plants found within each respective habitat, and will maintain a list of all plant species identified within the Project Area.

Plants will be identified to the species level if possible, or at a minimum, if the plant is outside its phenological peak, the plant will be identified to the genus level if species identification is not possible. If positive identification cannot be completed in the field, voucher samples can be collected, pressed, and preserved for further identification when appropriate. Prior to the 2014 field survey, biologists will obtain the necessary collecting permit for any voucher samples that may need to be collected from the State Botanist at the Massachusetts NHESP. Other general information that will be gathered during meander

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

surveys will include general health of communities, evidence of erosion, and site quality conditions. Vegetation communities will be classified using NHESP Classification of the Natural Communities of Massachusetts ([Swain & Kersey, 2011](#)). Palustrine habitats will be field-verified using the NWI as a base map. These areas will not be formally delineated, but will be further defined from the NWI using methods outlined in the ACOE Wetland Delineation Manual and the Regional Supplement to the *Corps of Engineers Wetland Delineation Manual: Northcentral and Northeast Region* ([USACE, 1987](#); [USACE, 2012](#)).

Sample vegetation plots within representative habitat types will also be established to collect quantitative information to characterize the different habitats and provide species composition of habitat types. Vegetation plot locations will be selected using NHESP guidelines and protocols. Sample vegetation plots will be completed for representative areas of Project-related vegetation management and recreational areas. These plots will be used to compare natural undisturbed habitats at the Projects to Project-affected habitats. A NHESP Quantitative Community Characterization Form (NHESP Form 3) will be completed for representative habitats to document the results of each plot location. Geo-referenced photographs will also be taken to document site conditions at the time of the survey.

To refine the vegetation type map for the study area, the following tasks will be performed:

- Acquire and compile existing GIS vegetation cover type, land use, and recreational layers from available resources;
- Examine any visible vegetation boundaries in aerial photos or other imagery to fix or update type polygon boundaries, based on field observations;
- Produce a final vegetation type map that displays vegetation type polygon boundaries, the study area, and specific Project components; and
- Use the vegetation type map to produce a table of vegetation types and calculate the percent acres of each vegetation type present in the study area in general, in areas potentially affected by the Project, and indirectly affected key wildlife habitats.

Task 4: Invasive Plant Survey

The MIPAG maintains a list of invasive plant species in Massachusetts and provides criteria used in evaluating species. The MIPAG species list of invasive plants will be utilized to identify targeted invasive species when conducting botanical meander surveys. Surveyors will use methods adapted from the NHESP and the United States Forest Service (USFS) Invasive Species Program, Invasive Species Inventory and Mapping Data Recording Protocols ([USFWS, 2010](#)). These adapted methods focus on presence, location, extent, abundance and other site characteristics to provide site infestation information.

To document an infested area, biologists will use a GPS at sub-foot accuracy to delineate the boundary of the infestation as defined by the dominant canopy cover of the invasive plant. Areas containing only occasional invasive species will be characterized with a GPS center point and radius necessary to enclose the population. For areas where invasive species are ubiquitous or impractical to map, surveyors will characterize the invasive species population using estimates of aerial coverage and percent of species present within a defined polygon. As land disturbances following Project maintenance activities may favor establishment of invasive plants over native plant communities, survey efforts for invasive species will be focused on disturbed lands, areas of vegetation management, access roads and recreational trails which can be vectors for invasive species propagation. Sampling areas containing invasive botanical species will be photo-documented with geo-referenced photos, and an Invasive Species Documentation Form will be completed.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 5: Land Management Practices and Recreation Uses

FirstLight will provide information to identify Project-related land management and maintenance practices and the usage of Project-related recreation areas. Annual maintenance activities are typically conducted during the growing season every year and may include vegetation management, erosion control, road maintenance, and other general project maintenance. This information will be analyzed with results from the wildlife and botanical field surveys at the Northfield Mountain Project to identify the relationship between Project facilities, recreational uses and wildlife and botanical resources and identify practices to avoid or minimize impacts.

Task 6: Data Analysis and Reporting

A draft and final technical report will be prepared for this study. The results of this study will provide both quantitative and qualitative information that will be important in defining existing conditions, as well as providing any information on potential project impacts as they relate to preparation of the License Application. The report will contain all supporting correspondence among licensing participants. The draft report will be revised to address final comments by licensing participants.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

This study would likely take one study season to complete. The estimated budget for the study ranges from approximately \$30,000 to \$40,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The Inventory will be conducted as follows:

- January – March 2014: Reviewing existing information and data
- April - August 2014: Conduct field reconnaissance surveys
- September - December 2014: Prepare data and report

3.5 Wetlands, Riparian, and Littoral Habitat**3.5.1 Baseline Inventory of Wetland, Riparian and Littoral Habitat in the Turners Falls Impoundment, and Assessment of Operational Impacts on Special-Status Species****General Description of Proposed Study**

This study contains multiple elements. In addition to conducting an inventory of wetlands, riparian and littoral zone resources in the Turners Falls Impoundment, the methods in this study contain provisions for assessing Project impacts on state-listed plant species in the Turners Falls Impoundment as well as downstream of Cabot Station, and assessing Project impacts on state-listed invertebrate species that utilize riparian areas downstream of Cabot Station.

Several stakeholder groups submitted a request to FirstLight to study impacts of water level fluctuations due to operations at the Turners Falls and Northfield Mountain Pump Storage Project on riparian, wetland and littoral zone resources in the Turners Falls Impoundment. The USFWS, Town of Gill, LCCLC, FRCOG, CRWC, VANR, NHFG, NHDES, and TNC study requests were similar and requested that the applicant complete studies to obtain baseline information on riparian, wetland, littoral zone, and shallow water aquatic habitats (subject to operational inundation and exposure to near exposure) known to occur in the Project area. Information would be used to determine whether riparian, wetland, submerged aquatic vegetation (SAV) and emergent aquatic vegetation (EAV), littoral, and shallow water (e.g., mid river bars and shoals) habitats are impacted by current water level fluctuations permitted under the license for the Turners Falls Project and Northfield Mountain Project. A baseline inventory will be conducted to map these resources and to determine if there is any unique or important shoreline or aquatic habitats in the Project area.

The MDFW also requested two additional studies related to the above requests. The first request (study request number 23) is to conduct a study to quantify the impacts of water level fluctuations and the current and proposed flow regimes on state-listed rare plant species in the Turners Falls Impoundment, and in the 13+ miles of riverine habitat below the Turners Falls Dam (to the Rt. 116 Bridge in Sunderland).

The second MDFW request (number 19) is to integrate modeled river flows and water levels with a habitat assessment for state-listed riparian invertebrate species. MDFW requested that the model should specifically assess the influence of existing and proposed Project operations on water levels at both known populations and potential habitats for the Cobblestone Tiger Beetle (*Cicindela marginipennis*), state-listed as “Endangered,” and the Puritan Tiger Beetle (*Cicindela puritana*), state-listed as “Endangered” and federally-listed as “Threatened”, and assess how Project operations may be modified to conserve and enhance existing populations and potential habitats.

As requested by the MDFW, this study will utilize the results of the Hydraulic Study as described in [Section 3.2.2](#) to quantify and assess potential impacts of Project-related water level fluctuations on existing wetlands, riparian and littoral habitat resources including state-listed plant and invertebrate species.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goals of this study are to characterize and describe the wildlife and botanical resources within the Project Area and assess the potential impacts of Project-related reservoir water level fluctuations on identified resources. The specific objectives of this study are to:

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Quantitatively describe and field verify National Wetland Inventory (NWI) mapped wetland types, describe and map shallow water aquatic habitat, including submerged aquatic vegetation (SAV) and emergent aquatic vegetation (EAV), substrate type, invasive species and associated wildlife in the Turners Falls Impoundment and up to 200 feet from the Turners Falls Impoundment shoreline within the Project boundary.
- Obtain baseline information, through field surveys, on the locations and population parameters of Massachusetts state-listed rare plant species in the Turner Falls Impoundment and the 13+ miles of riverine habitat below Cabot Station to the Rte. 116 Bridge in Sunderland.
- Analyze how the Project operations affect botanical and wildlife resources with an emphasis on how Project operations influence known or potential habitat of state-listed plant species and state-listed invertebrate species including the Cobblestone Tiger Beetle and the Puritan Tiger Beetle.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

This study will provide baseline information to agencies with jurisdiction over wetlands, riparian and littoral resources allowing them to address potential Project effects. The resource management goals identified are listed below.

Wildlife and freshwater fish resources are administered by USFWS, whose mission is to "conserve, protect and enhance and if needed mitigate fish, wildlife and plants and their habitats for the continuing benefit of the American people." In doing so, USFWS enforces wildlife laws, protects endangered species, manages migratory birds, and helps to restore important fisheries. They administer the ESA, designed to protect imperiled species from going extinct. Specific to the Turners Falls Project the Service goals are to:

- Protect, enhance, or restore diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Minimize current and potential negative Project operation effects on water quality and aquatic habitat.

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the MADFW. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions and protection of wetlands and aquatic habitats of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The MADFW resource goals and regulatory requirements are to:

- Ensure that protection mitigation and enhancement measures are commensurate with Project effects and meet MESA and the WPA requirements for the Project.
- Conserve, protect, and enhance habitats for state-listed species that will be affected by Project operations.

Massachusetts Invasive Plant Advisory Group (MIPAG), a committee where the Massachusetts Natural Heritage Endangered Species Program (NHESP) is represented, maintains a list of invasive plant species in Massachusetts and provides criteria used in evaluating species. The NHESP management goal is to promote the conservation and protection of species that are not hunted, fished, trapped or commercially harvested in Massachusetts. The NHESP highest priority is protecting the state-listed RTE species. The overall goal of the program is the protection of the state's wide range of native biological diversity.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

The VANR's resource management goals applicable to this study plan are:

- Protect, enhance, or restore, diverse high quality habitat necessary to sustain healthy aquatic and riparian plant and animal communities.
- Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize the potential negative effects of project operation on water quality and aquatic habitat, and mitigate for loss or degradation.
- Conserve, enhance, and restore Vermont's natural communities, habitats, and species and the ecological processes that sustain them.
- Provide a diversity of fish- and wildlife-based activities and opportunities that allow the safe and ethical viewing, regulated harvesting, and utilization of fish, plant and wildlife resources consistent with the North American model of fish and wildlife conservation.

The New Hampshire Department of Environmental Services is primarily interested in the portion of the Turners Falls Impoundment that is in New Hampshire. NHDES is responsible for ensuring that all state surface waters meet the water quality criteria for their designated classification, including existing and designated uses, and that the chemical, physical, and biological integrity of New Hampshire's surface waters is maintained [Env- Wq 1703.01 (b)].

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

The PAD provides lists of plant and wildlife species whose native ranges overlap with the Project area, but it does not provide any site-specific information on known occurrences of these species in the wetlands, riparian, littoral and shallow water habitats, within or adjacent to, the Project area. In addition, existing information in the PAD does not quantify EAV and SAV in the Project area, or other shallow aquatic habitat types and physical features (e.g., depths, substrates, wood structure) that are the environment for aquatic biota in the Project area.

Small areas of known invasive SAV beds are present in the Turners Falls Impoundment in the vicinity of Barton's Cove. FirstLight is currently cooperating with the USFWS on hand pulling water chestnut plants in this area. A very small colony exists on the Gill and Montague sides, located between the upstream side of the Dam and the boat barrier.

Additional site-specific data are needed to meet the goal of evaluating Project effects. Studies will supplement existing information regarding vegetation mapping, sensitive plants, invasive plants, and presence of RTE species or associated habitat.

Section 4.6 of the PAD contains information about wetland vegetation mapped in area of the Project, including NWI maps. Other available information including FEMA floodplain maps, USGS 7.5 minute quadrangles, NRCS soil surveys, and aerial photography. While this information provides baseline data for analysis, there are no known site-specific assessments or ground-mapping data of wetland habitats within the Project boundary. Additional site-specific data are needed to evaluate specific Project effects. Field studies will supplement existing information in the following areas:

10. Refine existing mapping, which will include field verifying the NWI mapping; and
11. Identify and classify existing wetlands and other "waters of the U.S." in accordance with USACE practices to define areas subject to federal regulation and policies.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

In preparation of the PAD, Federal and state agencies were contacted regarding the potential presence of RTE species and critical habitats within the Turners Falls Project and Northfield Mountain Project boundaries and included the USFWS, NMFS, Massachusetts NHESP, VTFWD, and NHFGD. The consultation resulted in the identification of three federally-listed threatened and/or endangered species (Section 4.7.1 of the PAD), 39 state-listed threatened and/or endangered species (Section 4.7.2 of the PAD), 21 state-listed species of special concern (Section 4.7.3 of the PAD) and designated critical habitat (Sections 4.7.4) that are likely or known to occur within the Project boundary and are detailed in Section 4.7 of the PAD.

Agency consultation revealed no federally designated critical habitat areas within the Turners Falls Project and Northfield Mountain Project areas; however, the Project areas are located within or on a portion of State designated Natural Areas classified as priority habitats and/or estimated habitats. Detailed information regarding habitat preferences and life histories of these species can be found in Section 4.7 of the PAD.

The MADFW commented that several surveys along this stretch of the River have shown that many state-listed plant species are dynamic local populations and often display meta-population dynamics, changing in size and location from year to year. The MADFW commented that this is particularly true for plant species inhabiting sand bars and high energy shore and cobble islands, including (but not limited to) the state-listed Wright's Spike-rush, Intermediate Spike-sedge, Ovate Spike-sedge, Frank's Lovegrass and Tufted Hairgrass. Large and/or rapid changes in water elevation and/or flow dynamics may cause adverse effects to existing and potential habitat for state-listed plant species. FirstLight is not aware of any studies that evaluate the effects of these changes in water level elevations on the life cycle of state-listed species and in particular, the germination, growth, and dispersal of species inhabiting mudflats, sand bars, and cobble islands. A list of NHESP state-listed species for the Project is provided in Table 4.7.2.5-1 in Section 4.7.2.5 of the PAD.

Additional information is needed to analyze how Project operations have or will alter hydrology in the Connecticut River from below the Vernon Hydroelectric Project downstream to the Holyoke Dam, or how operations have or may affect known wildlife and botanical resources. Of particular concern is how operations have or may affect known populations and potential habitats for state-listed invertebrate species, including the Puritan and Cobblestone Tiger Beetles.

Puritan tiger beetle and the cobblestone tiger beetle populations are limited in Massachusetts. The only known population of each species is found along the Connecticut River, with Puritan tiger beetle known from a single site at Rainbow Beach in Northampton, MA, and cobblestone tiger beetle known from a single site in Montague, MA (first observed in 2000). Detailed surveys of Puritan tiger beetle have been conducted at Rainbow Beach for adults and larvae from 1997 to the present (Davis, 2011²⁵).

Project Nexus (18 CFR § 5.11(d)(4))

The Turners Falls Project and Northfield Mountain Project provide a variety of wetland, riparian, and littoral habitat for a range of wildlife and botanical species. Water levels fluctuations have the potential to affect these water sensitive resources. An understanding of the locations and extent of resources in the Project area would provide information on the type and quantity of wildlife, plants, and habitat potentially affected by project operations. The current operating mode, as well as the unknowns with proposed upper reservoir expansion, may affect wetland riparian, littoral and other shallow water habitats and promote the introduction and expansion of invasive plant species through fluctuating water levels. A study that

²⁵ Unpublished report submitted to U.S. Fish & Wildlife Service, Turners Falls, MA.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

explains the relationship between the proposed mode of operation and the type and quantity of wetland, riparian, littoral, shallow water habitats, and invasive species affected would help inform a decision on the need for protection and/or control of these resources in the License.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

A field survey will be conducted within the Turners Falls Impoundment and below Cabot Station to document the type and distribution of wildlife habitats and vegetation communities present in the Project Area. The Study Area includes the following:

12. Turners Falls Impoundment and land up to 200 ft from the shoreline of the impoundment within the Project boundary extending from the base of Vernon Dam to the Turners Falls Dam.
13. The approximate 13+ miles of riverine habitat below the Dam to the Rte. 116 Bridge in Sunderland.

Field surveys will be conducted to observe conditions at the lowest water level operational range permitted on a daily operation schedule, under low flow conditions. In addition, the rate and height of water level changes resulting from Project operations during the field season will be cataloged to better understand the correlation of field observations and how they relate to field conditions during survey dates.

Task 1: Literature Review

Prior to the field reconnaissance surveys, existing information and data will be reviewed to identify areas of representative communities and potentially suitable habitat for protected species of interest. Using GIS and other available sources of information, a preliminary field map will be produced to assist field surveys. Pre-survey, biologists will review life histories of wildlife and phenology of listed plants for known listed species at the Project to select field survey windows to optimize observations.

Task 2: Riparian and Littoral Zone Botanical Survey

Botanical assessments will be completed to determine the species composition, structure, and distribution of vegetative communities. The types of data that will be collected include percent cover and dominant species within the herbaceous, shrub, and tree strata along with the general distribution and juxtaposition of vegetative communities. All botanical field inventories listed in this study will employ the concepts of timed-meander surveys, which will involve walking a wandering path through each representative habitat type and recording species present until a period of time (typically 10 minutes) passes where no new species were added to the vegetation list. Surveyors will compile a census list of all plants found within each respective habitat, and will maintain an overall list of all plant species identified within the Project Area. Plants will be identified to the species level if possible, at a minimum if the plant is outside its phenological peak, the plant will be identified to the genus level if species identification is not possible. If positive identification cannot be completed in the field, a voucher sample will be collected, pressed, and preserved for further identification when appropriate. Prior to the 2014 field survey, biologists will obtain the necessary collecting permit for any voucher samples that may need to be collected from the State Botanist at the Massachusetts NHESP. Other general information that will be gathered during meander surveys will include general health of communities and site quality conditions. Vegetation communities will be classified using NHESP Classification of the Natural Communities of Massachusetts ([Swain & Kersey, 2011](#)).

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Sample vegetation plots will also be established to collect quantitative information to characterize the different habitats and provide species composition of habitat types. Vegetation plot locations will be selected using Massachusetts NHESP guidelines and protocols. Massachusetts NHESP Quantitative Community Characterization Forms (Massachusetts NHESP Form 3) will be completed for representative habitats to document the results of each plot location. Geo-referenced photographs will also be taken to document site conditions at the time of the survey.

To refine botanical information for the study area, the following tasks will be performed:

14. Acquire and compile existing GIS vegetation cover type layers from available resources;
15. Examine any visible vegetation boundaries in aerial photos or other imagery to fix or update type polygon boundaries, based on field observations;
16. Produce a final vegetation type map that displays vegetation type polygon boundaries, the study area, and specific Project components;
17. Use the vegetation type map to produce a table of vegetation types and calculate the percent acres of each vegetation type present in the study area in general, in areas potentially affected by the Project, and indirectly affected key wildlife habitats.

During botanical surveys, incidental wildlife observations will be noted and reported consistent with [Study No. 3.4.1](#).

Task 3: Sensitive Plant Survey

A sensitive plant survey and completion of a biological evaluation on the locations and population parameters of Massachusetts state-listed rare plant species as identified in Section 4.7 of the PAD will be completed in the Turner Falls Impoundment and the 13+ miles of riverine habitat below the Dam to the Rte. 116 Bridge in Sunderland. This sensitive plant survey will utilize guidelines and modified protocols established by the Massachusetts NHESP, VDFW Wildlife Diversity Program, and the NHEFG Nongame and Endangered Wildlife Program. The sensitive plant survey will document state-listed plant species exhibiting meta-population dynamics and will focus more intensive field surveys on plant communities inhabiting mud flats, sand bars, and high energy shore and cobble island habitat types which are directly affected by water level fluctuations. The shoreline of the study area will be surveyed to locate all high probability areas that have suitable habitat and a high likelihood for sensitive plant associations. In identified areas having high likelihood of sensitive plants a timed-meander survey will be conducted for approximately 10 minutes to provide a census of the area. Species identified will be recorded for each site investigated and will also be added to the overall plant species census list for the Project.

The exact areas of focus will be determined after more extensive review of available information and based on professional judgment in the field. Areas having a known record of special status plants as determined in the pre-survey review and that may be affected by Project operations will be surveyed to cover 100 percent of the area. Positive identification of state-listed plant species will be photo-documented and GPS-located.

Task 4: Invasive Plant Survey

The Massachusetts Invasive Plant Advisory Group (MIPAG) maintains a list of invasive plant species in Massachusetts and provides criteria used in evaluating species. The MIPAG species list of invasive plants will be utilized to identify targeted invasive species when conducting botanical meander surveys.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Surveyors will use methods adapted from the USFS Invasive Species Inventory and Mapping Data Recording Protocols ([USFWS, 2010](#)). These adapted methods focus on presence, location, extent, abundance and other site characteristics to provide site infestation information.

To document an infested area, biologists will use a GPS at sub-foot accuracy to delineate the boundary of the infestation as defined by the dominant canopy cover of the invasive plant. Areas containing only occasional invasive species will be characterized with a GPS center point and radius necessary to enclose the population. For areas where invasive species are ubiquitous or impractical to map, surveyors will characterize the invasive species population using estimates of aerial coverage and percent of species present within a delineated polygon. As land disturbances following Project maintenance activities may favor establishment of invasive plants over native plant communities, survey efforts for invasive species will be focused on disturbed lands, areas of vegetation management, access roads and recreational trails, which can be vectors for invasive species propagation. All sampling areas containing invasive species will be photo-documented with geo-referenced photos, and an Invasive Species Documentation Form will be completed.

Task 5: Mapping Wetlands and Waters of the United States

Initial determination of wetland areas will be conducted through the use of existing information such as existing FirstLight site knowledge, NWI maps, FEMA floodplain maps, USGS 7.5 minute quadrangles, soil surveys, and aerial photography. This information will be transferred and digitized into GIS and preliminary wetland base maps will be prepared. This GIS wetland overlay will also be incorporated into an overall habitat or cover type map detailing all the habitat areas found in the project area or influenced by the Project.

Using the preliminary base wetland maps, field assessments will be completed to verify, classify and characterize the wetland communities. A team of qualified wetland biologists will complete the field assessments during the 2014 growing season when vegetation is most readily identifiable. Wetland habitats will not be formally delineated, but will be further defined from the existing NWI maps. Wetlands will be identified using standard federal criteria and methods outlined in the USACE Wetland Delineation Manual and the Regional Supplement to the USACE Wetland Delineation Manual: North Central and Northeast Region ([USACE, 1987](#); [USACE, 2012](#)). Wetland types mapped will be classified using the USFWS Cowardin wetland classification system (e.g., palustrine, unconsolidated bottom, riverine aquatic bed) ([Cowardin et al., 1979](#)). General wetland verification and mapping will be completed using a GPS at sub-foot accuracy. Points collected in the GPS will be transferred to the GIS data base to assist in the creation of the final wetland presentation including location, type, and extent.

Evaluations and analysis of wetland functions and values will use the standard USACE descriptive approach (also known as the ACE Highway Methodology) ([USACE, 1999](#)). The ACE method is a descriptive (qualitative) approach for evaluating the functions and values of wetlands, which directs the user to identify the functions and values associated with a particular wetland based on the presence or absence of certain characteristics. For each wetland type, standard data will be recorded for the most important biotic and abiotic characteristics as the basis for identifying important wetland functions and values. This assessment will be completed holistically for each wetland type. A functional analysis of each wetland is not necessary because wetland "types" are functionally similar. Investigators will identify the "principal" or important functions and values associated with each wetland or wetland type.

Task 6: Project Water Level Fluctuation Assessment

A HEC-RAS model in an unsteady state will provide data to determine the contribution of water level fluctuations associated with Project operations. This hydraulic model will be developed as part of [Study](#)

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

No. 3.2.2. Specifically, this information will be used to address how hydraulically connected habitats and vegetation is affected.

A cross-section will be established in known areas of cobblestone tiger beetle and Puritan tiger beetle habitat for use in conjunction with the model results. The cross-section information will include depth and substrate measurements. The model output will provide information on water level elevation changes in relation to Connecticut River flows under a variety of test conditions

Task 7: Data Analysis

Following field surveys, GIS-based maps will be developed depicting wetland habitats, SAVs, EVAs, invasive species, RTEs, and other related information collected during the study. The field data collected will be geo-referenced as polygons or point data and overlain on orthophotos at a suitable scale. Field data will then be subject to QA/QC procedures, including spot-checks of transcription and comparison of GIS maps with field notes to verify locations of wetland sites and wetlands found. The results of this study will provide both quantitative and qualitative information that will be important in defining existing conditions, as well as providing any information on potential Project impacts as they relate to preparation of the License Application. This study is consistent with methodologies of generally accepted scientific practices and uses standard federal wetland assessment methods developed and used by Federal land management agency personnel.

Task 8: Reporting

A draft report will be prepared for study team review and comment, documenting methods and results. The report will provide the baseline information to defining existing conditions as well as analytical discussions and conclusions of potential Project impacts. The report will contain appendices of survey data and supporting correspondence among licensing participants. The report will be finalized following receipt of input from the study team and revisions to address any final comments by licensing participants.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

This study will likely take one study season to complete and will be conducted during the 2014 field season. The estimated cost for the study could range from approximately \$60,000 to \$80,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

The Wildlife and Botanical Inventory will be conducted as follows:

- January – March 2014: Reviewing existing information and data
- April - August 2014: Conduct field reconnaissance surveys
- September - December 2014: Prepare data and report

3.6 Recreation and Land Use*3.6.1 Recreation Use/User Contact Survey***General Description of Proposed Study**

This study was originally proposed as part of the PAD. FERC has requested a Recreation Facility Inventory and Use and Needs Assessment. In particular, FERC requested that FirstLight conduct a study to determine the existing use and demand at the projects and an assessment of the need to enhance recreation opportunities and access at the Projects. FERC proposed that the data be collected using on-site visitor intercept surveys at formal and informal public recreation areas at the Project reservoirs, tailraces, and riverine areas, including the Turners Falls bypassed reach; and mail and/or internet surveys targeting unique stakeholder groups that may not be practically accessed through on-site surveys (e.g. adjacent residential landowners, residents of the counties in which the projects are located, rock climbers, whitewater boaters).

FirstLight proposes to conduct a user count at the Turners Falls Project and Northfield Mountain Project recreation sites using both pressure tube counters and visual counts, including calibration counts to support the tube counters. FirstLight also proposes to develop and conduct contact surveys to determine the views of the recreating public with regard to the available recreation sites and activities within the Turners Falls Project and the Northfield Mountain Project boundary and to also request zip code information to assist with determining user distribution. It is anticipated that conducting the contact surveys at formal recreation sites will capture use by the majority of Project recreation users, including use at informal sites. This is because the majority of individuals utilizing informal sites within the Projects will access the sites via formal recreation facilities.

In addition, FirstLight proposes to conduct a mail survey targeted at adjacent residential landowners. The targeted mail survey should capture the majority of recreational use that may not originate at formal and informal sites. FirstLight is not proposing to conduct a mail survey of residents of the counties in which the Projects are located because the high cost of a general mail survey outweighs the uncertain benefit of a mail survey. The results of county-wide surveys tend not to be representative of the general recreational user population and produce unreliable results. There are an estimated 97,844 households in the three counties in which the Projects are located. Depending on the survey return rate, the estimated cost of conducting a mail survey, using a modified Dillman method, for 97,844 households could range from \$700,000 to more than \$1,605,000.00. FirstLight is not proposing to conduct internet surveys as part of this study. Internet surveys are generally not appropriate for quantitative analysis because the results tend not to be representative of the general recreational user population and are not reliable.

FirstLight proposes to use the information from the *Recreation Use/User Contact Survey* in conjunction with the *Recreation Facilities Inventory and Assessment* ([Study No. 3.6.2](#)), the *Whitewater Boating Evaluation* ([Study No. 3.6.3](#)), the *Assessment of Day Use and Overnight Facilities Associated with Non-Motorized Boats* ([Study No. 3.6.4](#)), and the *Recreation Study at Northfield Mountain, including Assessment of Sufficiency of Trails for Shared Use* ([Study No. 3.6.7](#)) to determine the sufficiency of existing recreation facilities in meeting recreation demand at the Projects and to assess the need to enhance recreation opportunities and access at the Projects.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

The objectives of the study are:

- Determine the amount of recreation use and demand at the Turners Falls and Northfield Mountain recreation sites; and
- Interview the recreating public to determine user opinions and goals with regard to the recreation sites, including the perceived adequacy of recreation facilities and access at the Project.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreational opportunities associated with the operation of the Turners Falls and Northfield Mountains Projects.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))Existing Information:

Section 4.8 of the PAD provided information regarding recreation resources within the Projects and surrounding area. Recreation use at the Turners Falls Project and Northfield Mountain Project occurs in all seasons and includes motorized and non-motorized boating, fishing, camping, canoeing, climbing, sightseeing, hunting, skiing, hiking, walking, biking, horseback riding, and picnicking. There are multiple recreation facilities within the Projects' boundaries that offer a variety of recreation opportunities. In general, areas associated with the Turners Falls Project and the Northfield Mountain Project are open to the public for recreation use. There is no public access to the upper reservoir, and the reservoir is surrounded by a security fence. It can be viewed, however, from a platform on a nearby trail.

There are 20 formal recreation facilities located within the Turners Falls and Northfield Mountain Projects' boundary. These facilities provide a variety of amenities, including but not limited to boat ramps, camp sites, picnic tables, benches, trails, and interpretive displays. Lands within the Northfield Mountain Project contain Rose Ledge and Farley Ledges, which are routinely used by climbers.

The 2009 Form 80 for the Turners Falls Project reported that the total annual daytime use was 36,694 recreation days, and the total annual nighttime use was 4,584 recreation days. The peak weekend daytime average use was 339 recreation days, and the nighttime average was 27 recreation days. The interpretive displays were used at 80% of facility capacity, while the trails were used at 5% of their capacity. Parks and picnic areas in the Project were used at 35% of the facility capacities. The canoe portage and tailwater fishing facilities were used at 10% of their capacities.

The 2009 Form 80 for the Northfield Mountain Project reported that the total annual daytime use was 71,672 recreation days, and the total annual nighttime use was 4,564 recreation days. The peak weekend daytime average was 2,360 recreation days, and the nighttime average was 207 recreation days. The tent/trailer/RV sites and group camps were used at 80% of the facilities' capacities, while the interpretive displays were used at 20% of their capacity. The parks were used at 28% capacity, trails were used at 25% capacity, picnic areas were used at 24% capacity, and the Tour and Trail Center was used at 50% capacity.

Need for Additional Information:

Information on current use and whether existing access facilities in the area are meeting recreation demand would inform a decision on whether additional, designated public access at the Projects is necessary to meet existing and future recreation demand at the Projects.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Project Nexus (18 CFR § 5.11(d)(4))

FERC regulations require that the license application include a statement of the existing recreation measures or facilities to be continued or maintained and the new measures or facilities proposed by the applicant for the purpose of creating, preserving, or enhancing recreational opportunities at the Projects and in their vicinities, and for the purpose of ensuring the safety of the public in its use of Project lands and waters. In addition, recreation is a recognized project purpose at FERC-licensed projects under section 10(a) of the FPA.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

To determine the amount of recreation use at the Projects, the Licensee proposes to conduct a recreation use study in combination with a user contact survey and mail survey.

Task 1: Study Preparation

FirstLight will develop a user contact survey, determine the survey dates and times. All sampling days will be randomly selected and survey routes will be completed on a rotating basis and at different times of day to account for time-of-day use patterns. FirstLight also will develop a mail questionnaire/survey, based on Dillman approaches for developing mail surveys, which will be designed to ascertain recreational use by residential abutters.

Task 2: Field Work

The recreation use study will occur over four seasons in order to capture recreational use occurring in spring, summer, winter, and fall. It will be conducted using a combination of tube counters, calibration counts, spot counts, and actual use numbers. Tube counters will be placed at high use facilities within the Projects. These will be used to obtain an estimate of the number of vehicles using the site. The counters will be checked on Friday afternoon and Monday mornings to differentiate between weekday and weekend use. Calibration counts will be conducted at each formal Project recreation facility and will be documented on a survey form. These counts will last for at least two hours per site on each calibration day. This information will be used to verify that the traffic counters are functioning properly, determine the average number of individuals per vehicle, and determine the type of recreation use individuals are participating in. The spot counts will be conducted at all formal recreation areas within the Project. This information will be documented on a survey form. The spot counts will record the number of vehicles parked at a facility to determine the time-of-day use patterns at the sites. FirstLight currently charges a fee for winter recreation use at the Northfield Mountain Project and for their interpretive riverboat cruises. This information will be combined with the collected field data, when developing the user figures for the Projects. Final recreation use for the formal recreation facilities within the Projects will be summarized by season and activity type for each site. FirstLight will work with State agencies and private groups (e.g., Franklin County Boat Club, Turners Falls Rod and Gun Club, and Northfield Mount Hermon School) that manage existing public and private recreation facilities within the Project boundaries to determine use at their facilities.

A user contact survey will be developed to determine user opinions and goals with regard to the existing Project recreation facilities and opportunities such as whitewater and other boating opportunities, overnight camping, trail use, and rock climbing. The user contact survey will take place over the course of four seasons. The survey will also ask for the individuals' zip code to determine how far existing users travel to visit the Projects for recreational purposes. This information will also be used to determine length of stay, number of people in a party, and the opinion of the user with regard to the amount and

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

types of recreation opportunities offered within the Projects' boundaries. The survey will be administered during the calibration and spot count site visits.

A mail survey, using a modified Dillman method, will be mailed in the spring to residential abutters and a follow-up reminder card will be mailed out approximately two weeks later to those residences who have not returned a survey. It is assumed that approximately 25-40% of the targeted mail surveys will be completed and returned.

Task 3: Data Entry and Statistical Analysis

Information collected during Task 2 will be entered into spreadsheets for statistical analysis. Information such as the number of recreation days spent at the Projects' recreation sites, length of stay, average number of persons per party, and the percent of the facilities' capacity that is currently being utilized will be determined.

Task 4: Report Writing

The information that is gathered during this effort will be used to complete both the recreation and land management portions of the license application, as well as the FERC Form 80. Information from this study will be incorporated into a Recreation Management Plan along with information from several other studies.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort is sufficient to obtain baseline information on recreational usage and demand within the Projects' area. The estimated cost for the recreation inventory and user contact survey outlined in this plan is approximately \$85,000-\$95,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. Field data collection will take place in 2014. Statistical analysis of the data will occur in 2015.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.6.2 Recreation Facilities Inventory and Assessment**General Description of Proposed Study**

The majority of this study was conducted in 2011 and 2012 in order to collect baseline information on recreation facilities associated with the Projects and a summary of the results were originally presented in the PAD. Due to low snow years in 2011 and 2012, the winter field work of this baseline survey was not conducted until March 2013. This study was designed to confirm the number of existing recreation facilities, the number and types of amenities available at each facility and the overall condition of the facilities. In its study requests, FERC requested information on the condition of existing recreation facilities and access sites at the Projects. The intent of the proposed study is to prepare a summary report that identifies the number of existing recreation facilities and access sites, and the amenities and the overall condition of the facilities and access sites.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The objective of this study is to complete the baseline investigation of the existing recreation facilities within the Turners Falls Project and Northfield Mountain Project boundary with the preparation of a summary report of the results.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreation opportunities associated with the presence and operation of the Turners Falls and Northfield Mountain Projects.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))**Existing Information:**

There are 20 formal recreation facilities located within the Turners Falls and Northfield Mountain Projects' boundary. These facilities provide a variety of amenities, including but not limited to boat ramps, camp sites, picnic tables, benches, trails, and interpretive displays. Below is a brief description of each of the recreation facilities located within the Turners Falls and Northfield Mountain Projects' boundary.

Cabot Woods Fishing Access: This site is located within the Turners Falls Project on Migratory Way in Montague, MA. This site is owned and managed by the Licensee and is open to the public for day use activities such as fishing, hiking, and picnicking. There are picnic tables, three ADA parking spaces, and 17 parking spaces available at the site.

Turners Falls Branch Canal Area: This site is located within the Turners Falls Project, off of Power Street in Montague, MA. This site is owned and managed by the Licensee and is open for fishing. Parking and benches are available at this site.

Turners Falls No. 1 Station Fishing Access: This site is located within the Turners Falls Project, off of Power Street in Montague, MA. This site is owned and managed by the Licensee and is open for fishing. Parking is available.

Unity Park: This park is located within the Turners Falls and Northfield Mountain Projects, on either side of First Street in Montague, MA. This site is owned by the town of Montague, with a portion on the east side that is owned by the Licensee. The park facilities located on the south side of the road are managed

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

by the town of Montague, while the portion of the park located between the river and the road is managed by the Licensee. The park offers day use activities including walking, fishing, sightseeing, picnicking, and biking. Amenities at the park include restrooms, a playground, parking, ballfields, a basketball court, a paved trail, benches, and picnic tables.

Canalside Trail Bike Path: This bike trail is located within the Turners Falls Project along the Turners Falls Power Canal in Montague, MA. The trail property is leased to and managed by the MA Department of Environmental Management (now MA Department of Conservation and Recreation) and is open for non-motorized public use.

Turners Falls Fishway Viewing Area: This site is located within the Turners Falls and Northfield Mountain Projects, off of First Street in Montague, MA. The fishway is managed by the Licensee and is located at the southern end of Unity Park. The facility is open to the public in the spring to watch migrating fish.

Barton Cove Nature Area and Campground: This Nature Area is located within the Turners Falls and Northfield Mountain Projects, on Barton Cove Road in Gill, MA. The Nature Area is owned and managed by the Licensee and is open to the public for camping, picnicking, and bank fishing. Campsites have a picnic table, fire ring and garbage can. There are two vault toilets and additional portable restrooms located within the campground. There is water access from some of the sites and bank fishing is permitted.

MA State Boat Launch: This launch is located within the Turners Falls and Northfield Mountain Projects, off of Route 2 in Gill, MA. This site is owned and managed by the state of Massachusetts, and is open to the public. The site offers boat launching and bank fishing opportunities. There is a parking lot, boat ramp, dock, and portable sanitation facility.

Barton Cove Canoe and Kayak Rental Area: This site is located within the Turners Falls and Northfield Mountain Projects, off of Route 2 in Gill, MA. This site is owned and managed by the Licensee and offers day use opportunities. There is a canoe/kayak launch, a rental office, picnic tables, parking, and a portable sanitation facility.

Cabot Camp: This camp is located within the Turners Falls and Northfield Mountain Projects, at the end of Mineral Road in Montague, MA. The site is owned and managed by the Licensee and is open to the public as an informal bank fishing area. There is a large parking area and access to a local bike trail from the site.

Northfield Mountain Boat Tour and Riverview Picnic Area: This picnic area is located within the Northfield Mountain Project, off Pine Meadow Road in Northfield, MA. This site is owned and managed by the Licensee, and is available for day use activities including interpretive riverboat cruises, picnicking, and bank fishing. The site is accessible from the water and via a paved road. There is a formal parking lot available for those using the site and those who are boarding the riverboat. There are picnic tables, grills, sanitation facilities, and a boat dock at the site.

Northfield Mountain Tour and Trail Center: This site, which is also known as the Visitor Center, is located within the Northfield Mountain Project, off Millers Falls Road (Rt. 63) in Northfield, MA. The Center is owned and managed by the Licensee and is available for day use activities. Available opportunities include viewing interpretive displays, picnicking, and educational programs. The Center has restrooms, cross-country ski rental equipment, and parking. It is open for year-round recreational and educational use.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Northfield Mountain Trail System: The trail system is located at the Northfield Mountain Project, off Millers Falls Road (Rt. 63) in Northfield, MA. Over twenty-six miles of trail are available for hiking, biking, horseback riding, snowshoeing, and cross-country skiing.

Northfield Mountain Mountaintop Observation Area: This site is located adjacent to the Northfield Mountain Project upper reservoir. The Observation Deck is owned and managed by the Licensee and is accessible by hiking the trail system.

Munn's Ferry Boat Camping Recreation Area: This site is a water access site located on the east side of the river in Northfield, MA. The camping area is located within the Turners Falls and Northfield Mountain Projects. This area is owned and managed by the Licensee and is available for overnight use. There are tent campsites each with a trash can, tent platform, picnic table, fire ring and grill. There is also a lean-to site with a trash can, tent platform, picnic table, fire ring and grill. There are pit toilets available at the site. Bank fishing opportunities are also available at this site.

Bennett Meadow Wildlife Management Area (WMA): The Bennett Meadow WMA is managed by the state of Massachusetts, Division of Fisheries and Wildlife. The site is located within the Turners Falls and Northfield Mountain Projects. This site offers day use opportunities; it is open for hunting, and is also used for walking and hiking.

Pauchaug Boat Launch: This site is owned and managed by the state of Massachusetts. The site is located within the Turners Falls Project and Northfield Mountain Project. There is a boat launch, parking and portable sanitation available at this site.

Pauchaug WMA: This WMA is owned and managed by the state of Massachusetts, Division of Fisheries and Wildlife. This site is similar to the Bennett Meadow WMA and is located within the Turners Falls Project and Northfield Mountain Project. The site is open for hunting and is used for walking/hiking and bank fishing.

Governor Hunt Boat Launch/Picnic Area: This site is owned and managed by TransCanada, which owns the Vernon Project. While this area is within the Vernon Project boundary, the area is also located in the area where the Turners Falls Project and Northfield Mountain Project boundaries and the Vernon Project boundary overlap. The area is open for day use opportunities and has a picnic area and boat launch. Recreation opportunities at the site include bank fishing, picnicking, boat launching, and sightseeing.

Turners Falls Canoe Portage: Portages around the Turners Falls Dam are available seven days per week for canoes and kayaks. The portage take-out is at the Barton Cove Canoe & Kayak Rental Area. Boaters wishing to proceed downriver of Barton Cove are picked up by the Licensee and driven to just downstream of the Project on Poplar Street in Montague City, where they can continue their trip.

Project Nexus (18 CFR § 5.11(d)(4))

FERC regulations require that the license application include a statement of the existing recreation measures or facilities to be continued or maintained and the new measures or facilities proposed by the applicant for the purpose of creating, preserving, or enhancing recreational opportunities at the Projects and in their vicinities, and for the purpose of ensuring the safety of the public in its use of project lands and waters. In addition, recreation is a recognized project purpose at FERC-licensed projects under section 10(a) of the FPA.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

As stated in the PAD, the bulk of this study was conducted in 2012 and a summary of the results was included in Section 4.8.1. The winter portion was completed in 2013 and a summary of the results for all four seasons of investigation will be prepared.

Task 1: Study Preparation and Field Work

FirstLight developed a standardized survey form to evaluate each existing recreation facility to determine its current condition and available amenities. Photos and GPS data was recorded while in the field for each facility. Once the work was completed this information was then entered into a GIS format.

Task 2: Summary Development

A summary of the results of the two studies will be prepared, along with maps of the recreation facility locations. FirstLight proposes to use this information in conjunction with [Study No. 3.6.1](#) the *Recreation Use/User Contact Survey*, the *Whitewater Boating Evaluation* ([Study No. 3.6.3](#)), the *Assessment of Day Use and Overnight Facilities Associated with Non-Motorized Boats* ([Study No. 3.6.4](#)), and the *Recreation Study at Northfield Mountain, including Assessment of Sufficiency of Trails for Shared Use* ([Study No. 3.6.7](#)) to assess the sufficiency of existing recreational facilities. This information will also be included in the Recreation Management Plan.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The cost to complete the remaining portion of this study is estimated at \$15,000-20,000. FirstLight believes that this is sufficient to fully meet the goals of this study.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.6.3 Whitewater Boating Evaluation**General Description of Proposed Study**

FERC, NEF, AMC, AWWA, NPS, VRC and FCRP submitted requests for a controlled flow whitewater boating analysis of the Turner Falls bypass reach. All the requests were similar and requested FirstLight to use accepted whitewater boating evaluation practices to assess the presence, quality, and preferred flow ranges for river based boating resources in the Turner Falls bypass reach. FERC also requested that competing recreational uses and resource needs that may be adversely impacted by any scheduled releases be identified. NEF, AMC, AWWA, NPS, VRC and FCRP also request that access needs for put-in and take-out along the bypass reach be identified and a flow information and distribution system be assessed. FirstLight is proposing to develop and conduct a controlled whitewater boating analysis of the Turner Falls bypass using accepted comparative evaluation practices. FirstLight will consult with stakeholders to develop a comparison flow study methodology, determine the number of flows and volumes to be evaluated, schedule the timing of the evaluation, and to enlist a group of experienced boaters to participate in the evaluation.

NEF, AMC and AWWA request that the flow assessment occur on various dates in the spring (for moderate and high flows) and in the summer (for potential scheduled lower flow releases). FirstLight is not proposing to conduct whitewater boating evaluations in the spring because the only known spawning and rearing areas for ESA-listed shortnose sturgeon in the Connecticut River are located in the bypass reach and whitewater flow releases have a potential to interrupt spawning or flush eggs and larvae from the rearing area. In addition, FirstLight does not propose to conduct a spring evaluation because of the possibility of unreliable results due to the lag time between spring and summer evaluations. Because a component of the boating evaluation will be a comparative rating and analysis of several flows, FirstLight is proposing that the on-water boating evaluation be conducted on consecutive days in one season to ensure consistency in assessing and comparing the various flows and in the make-up of the flow evaluation team.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The objectives of the study are:

- Assess the effects of a range of bypassed reach flows on whitewater recreation opportunities;
- Determine what whitewater boat-types would be appropriate to utilize any potential whitewater flows in the bypassed reach;
- Determine the range of flows (minimum through optimal) needed to support various whitewater boating opportunities by watercraft;
- Determine whether current or future demand exists for whitewater boating in the bypassed reach;
- Determine the number of days per month the acceptable and optimum flows for whitewater boating would be available under the Turners Falls Project's current and any proposed mode of operation;
- Determine any competing recreational uses or other resource needs that may be adversely affected by whitewater boating;
- Identify the need for and define adequate access points, if needed, that provide trails and car-top parking at Great Falls Discovery Center, Station #1 and Cabot Station, and egress at the end of the 2.7 mile bypass run at the confluence of the Deerfield River;

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

- Conduct an assessment of existing regional whitewater boating opportunities; and
- Prepare a study report that describes the: whitewater boating attributes of the range of flows examined, including level of difficulty, portage requirements; identifies the acceptable and optimal flows for the reach and the frequency of availability of the identified flows under current and any proposed project operation; incorporates relevant results from the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)), the *Recreation Facilities Inventory and Assessment* ([Study No. 3.6.2](#)), and the *Assessment of Day Use and Overnight Facilities Associated with Non-Motorized Boats* ([Study No. 3.6.4](#)) including characterization of the suitability of the bypassed reach for whitewater boating, annual recreation use by activity and season of the bypassed reach; whether or not there is a demand for whitewater boating in the bypassed reach; and any competing recreation uses or other resources in the bypassed reach that could be adversely affected by providing flows for whitewater boating.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreational opportunities associated with the presence and operation of the Turners Falls and Northfield Mountains Projects.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))Existing Information:

There is limited information on whitewater boating flows associated with the Turner Falls bypass. The Appalachian Mountain Club *AMC River Guide, Massachusetts, Connecticut, Rhode Island*, Fourth Edition (2006) states there is very little water in the bypass reach except during flood conditions when canoeing is not advised, and that the 3.5 miles of river below the Turner Falls Dam cannot be run even by experienced canoeists.

Anecdotal information indicates that whitewater features exist during high flow conditions in the bypass near the river bend just downstream of Turner Falls Dam and at the so-called “rock dam” located approximately 1.8 miles downstream of the dam, and that the remainder of the bypass is fast current.

Need for Additional Information:

To determine if flows in the bypass area can provide whitewater boating opportunities, a variable flow evaluation will need to be conducted.

Project Nexus (18 CFR § 5.11(d)(4))

FERC policy requires licensees to provide reasonable public recreation opportunities consistent with the safe and effective operation of the Project.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))Task 1 – Develop Boating Evaluation Protocol, Logistics and Schedule

Working with NEF, AWWA and AMC, and other interested stakeholders, FirstLight will coordinate selecting bypass flows (approximately four), scheduling of the evaluation (estimate two consecutive days), assembling a team of volunteer expert boaters, field logistics, and developing a methodology and comparative evaluation process to rate the bypass flows to meet the study objectives. FirstLight will

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

inspect the bypass reach for the presence of rebar in areas subject to flows, and if found, remove the rebar prior to the boating evaluation.

Task 2 – On-Water Boating Evaluation

The boating evaluation will be conducted as designed in Task 1. Though flows to be evaluated will be established prior to the field evaluations, flows may be adjusted based on participant boater recommendations during the evaluation provided any adjusted flow(s) can be calibrated at Turner Falls Dam. Participating boaters will complete an evaluation form after each flow and a comparative summary evaluation for all flows upon completion of the field evaluation. FirstLight will lead a post evaluation discussion to discuss the study and to gather additional feedback from the participants.

Task 3 – Identify and Evaluate Access to the Turner Falls Bypass Reach

FirstLight will identify, investigate, and assess access points that provide trails and car-top parking along the bypass reach including the Great Falls Discovery Center, Station #1, Cabot Station, and at the end of the 2.7 mile bypass run at the confluence of the Deerfield River. This work may be conducted as part of the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)).

Task 4 – Data Review and Analysis

Historic flow data will be analyzed to determine the number of days per month the acceptable and optimum flows for whitewater boating, as determined by the results of the controlled flow analysis, would be available under the Turner's Falls Project's current mode of operation. An analysis will also be conducted to determine the number and timing of boatable flows for any proposed mode of operation at Turner Falls.

FirstLight will assess whether current or future demand exists for whitewater boating in the bypassed reach using data from the controlled flow analysis, the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)), an assessment of existing regional whitewater boating opportunities, and regional projections for changes for paddle boating.

Based on existing data and data collected from other relicensing studies related to the Turner Falls bypass, FirstLight will identify any competing recreational uses or other resource needs that may be adversely affected by any scheduled releases for boating.

Task 5 – Report Development

The information gathered during these efforts will be included in a study report addressing the study goals and objectives identified above.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort is sufficient to obtain data to determine the level of whitewater boating opportunities, which may be available with releases in the Turner Falls bypass. The estimated cost for the whitewater boating evaluation outlined in this plan is approximately \$45,000 to \$50,000.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The Whitewater Boating Evaluation will be conducted in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.6.4 Assessment of Day Use and Overnight Facilities Associated with Non-motorized Boats***General Description of Proposed Study**

A number of stakeholders requested this study including NPS, AMC, VRC, FCRP, NEF, AWWA, and CRWC. As part of its request for a study of project facilities to support multiple-day self-powered boating trips, NPS/AMC et al request a survey of people who do not use the river or are displaced. FirstLight has proposed to conduct a study of recreation use at the Northfield Mountain Project but does not propose to conduct a survey of non-users or displaced users. It is difficult to identify with any degree of precision the scope of non-users and displaced users and target these groups for a survey. A regional blanket mail survey (to some portion of the populations) to reach these users requires a significant level of effort that is not justified by the typical low rate of return when considering the ratio of non-users and displaced users in relation to the population sampled. In sum, the survey may not provide a statistically valid sample size. FERC regulations require the Licensee to provide an estimate of existing and potential recreational use of the project area as well as measures for creating, preserving and enhancing recreational opportunities at the project. The proposed study plans use standard, FERC- accepted methodologies including a review of the existing day use and overnight facilities associated with carry-in boat launching and water-access camping within the Turners Falls and Northfield Mountain Projects.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

The objectives of the study are:

- Determine the number of overnight recreation facilities located within the Projects including the number, capacity, and types of amenities available;
- Determine the need for and if alternate canoe portage trails are feasible;
- Determine the need for and possible locations for future carry-in boat facilities (particularly at Turners Falls Dam, Station #1, Cabot Station, and the Deerfield River Confluence) and overnight facilities;
- Determine if current facilities are adequately spaced for non-motorized boating day use trips;
- Determine if improvements are necessary at existing facilities to meet current and near future use particularly at put-in and take-out facilities; and
- Determine if the seasons of operation are consistent with actual river use.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreational opportunities associated with the presence and operation of the Turners Falls Project.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))Existing Information:

Boating, camping, and canoeing use currently occurs within the Projects. The Connecticut River National Blueway, which encompasses the river and its 7.2 million-acre watershed includes Project lands and waters. The AMC River Guide and the Connecticut River Boating Guide: Source to Sea (3rd ed.) describe the Connecticut River between the Vernon Falls Dam and the Turners Falls Dam as a flat water to quick water paddle with overnight camping available at Munn's Ferry and Barton Cove Campground.

There are multiple recreation facilities within the Projects' boundaries that offer a variety of recreation opportunities to the boating community, including the following existing facilities.

Barton Cove Nature Area and Campground: This Nature Area is located within the Turners Falls and Northfield Mountain Projects, on Barton Cove Road in Gill, MA. The Nature Area is owned and managed by the Licensee and is open to the public for camping, picnicking, and bank fishing. Campsites have a picnic table, fire ring and garbage can. There are two vault toilets and additional portable restrooms located within the campground. There is water access from some of the sites and bank fishing is permitted.

MA State Boat Launch: This launch is located within the Turners Falls and Northfield Mountain Projects, off of Route 2 in Gill, MA. This site is owned and managed by the state of Massachusetts, and is open to the public. The site offers boat launching and bank fishing opportunities. There is a parking lot, boat ramp, dock, and portable sanitation facility.

Barton Cove Canoe and Kayak Rental Area: This site is located within the Turners Falls and Northfield Mountain Projects, off of Route 2 in Gill, MA. This site is owned and managed by the Licensee and offers day use opportunities. There is a canoe/kayak launch, a rental office, picnic tables, parking, and a portable sanitation facility.

Munn's Ferry Boat Camping Recreation Area: This site is a water access site located on the east side of the river in Northfield, MA. The camping area is located within the Turners Falls and Northfield Mountain Projects. This area is owned and managed by the Licensee and is available for overnight use. There are tent campsites each with a trash can, tent platform, picnic table, fire ring and grill. There is also a lean-to site with a trash can, tent platform, picnic table, fire ring and grill. There are pit toilets available at the site. Bank fishing opportunities are also available at this site.

Pauchaug Boat Launch: This site is owned and managed by the state of Massachusetts. The site is located within the Turners Falls Project and Northfield Mountain Project. There is a boat launch, parking and portable sanitation available at this site.

Governor Hunt Boat Launch/Picnic Area: This site is owned and managed by TransCanada, which owns the Vernon Project. While this area is within the Vernon Project boundary, the area is also located in the area where the Turners Falls Project and Northfield Mountain Project boundaries and the Vernon Project boundary overlap. The area is open for day use opportunities and has a picnic area and boat launch. Recreation opportunities at the site include bank fishing, picnicking, boat launching, and sightseeing.

Turners Falls Canoe Portage: Portages around the Turners Falls Dam are available seven days per week for canoes and kayaks. The portage take-out is at the Barton Cove Canoe & Kayak Rental Area. Boaters wishing to proceed downriver of Barton Cove are picked up by the Licensee and driven downstream to Poplar Street in Montague, where they can continue their trip.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Project Nexus (18 CFR § 5.11(d)(4))

FERC regulations require that the license application include a statement of the existing recreation measures or facilities to be continued or maintained and the new measures or facilities proposed by the applicant for the purpose of creating, preserving, or enhancing recreational opportunities at the Projects and in their vicinities, and for the purpose of ensuring the safety of the public in its use of Project lands and waters. In addition, recreation is a recognized project purpose at FERC-licensed projects under section 10(a) of the FPA.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Literature Review:**

FirstLight proposes to conduct a desk top review of the existing recreation data including recreation facility inventory data collected in 2012-2013 and camping records. This information will be used to determine the locations and spacing between facilities associated with non-motorized boating trips, as well as hours and seasons of operations. Data regarding existing capacity and existing campsite use will be compared to determine if the current facilities are meeting current use needs. The Licensee will review and take into consideration appropriate federal, state, county and local programs and plans related to recreational use of the waterway within the Projects' boundaries. Data from the *Recreation Use/User Contact Survey* will be reviewed to assess the need for new or improved facilities to accommodate non-motorized boating use at the Projects. FirstLight will also review land ownership information, existing improvement plans, and aerial photography to determine potential locations for future use sites, if needed and potential improvements for existing sites, if needed.

Task 2: Field Work

A field survey will be used to ground verify the location for potential future use sites and determine the feasibility of developing these sites. A review of potential canoe portage trails will also be conducted in the field along with flows at potential put-in locations. FirstLight will observe water flows and depths in the by-pass to determine navigability by non-motorized boats.

Task 3: Report Preparation

Upon completion of field surveys, FirstLight will use the data reviewed and gathered to develop a written report discussing the findings including the sufficiency of current recreation facilities and need, if any, for new or improved facilities and potential improvements with respect to multiple day non-motorized boat trips. A map depicting the current locations of facilities and potential future locations will also be included as part of the report.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort is sufficient to obtain information regarding carry-in boating opportunities within the Turners Falls Project area. The estimated cost for the assessment outlined in this plan is approximately \$20,000-25,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering

Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

PROPOSED STUDY PLAN

and study requests. The *Assessment of Day Use and Overnight Facilities Associated with Non-motorized Boats* will be in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.6.5 Land Use Inventory

General Description of Proposed Study

This study was proposed by FirstLight as part of the PAD and includes a review of existing land uses occurring on Project and adjacent lands, applicable land use controls such as local zoning, results of other resource studies, and a determination of the appropriate land use designations for lands within the Turners Falls Project and Northfield Mountain Project. Once the existing land uses and land use controls are identified, FirstLight will review available aerial photography and apply an appropriate designation to the Turners Falls Project and Northfield Mountain Project lands. This will aid in future land management decisions for lands within the Turners Falls Project and Northfield Mountain Project boundaries.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

The objectives of this inventory are as follows:

- Identify the current land uses within the Turners Falls Project boundary and the Northfield Mountain Project boundary.
- Identify the current land uses on lands abutting the Turners Falls and Northfield Mountain Project boundaries up to 200 feet.
- Identify current land use controls on lands within the Projects' boundaries and on lands abutting the Project boundaries up to 200 feet.
- Determine the appropriate land use designations for lands within the Turners Falls Project and Northfield Mountain Project boundaries. Designations will be based on the review of existing uses on lands within the Projects' boundaries and adjacent lands, the results of other resource studies, and land use controls such as local zoning.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

Resource management agencies are interested in the appropriate land designations in order to protect the natural resources within the Northfield and Turner Falls Projects.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))**Existing Information**

Section 4.8 of the PAD provided information regarding recreation resources within the Projects and surrounding areas. Lands within the Projects' boundaries are used for operation of the Projects and recreation. There are also areas of agricultural and forested lands, as well as wetland areas located within the Projects. Other land types located within the Projects include open land, medium, low, and very low density residential development, forest, wetlands, open land, powerline/utility, urban, public/institutional, and industrial uses. Associated land use activities also include land maintenance, road and trail maintenance, tree removal, and vegetation clearing. The area surrounding the Turners Falls and Northfield Mountain Projects, from the Northfield Mountain Project north to the Vernon Project, is

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

largely rural with a mix of agriculture lands and some forested areas. The lands south of the Northfield Mountain Project, near the Turners Falls Dam, are largely developed with a mix of residential and industrial uses. There are no Vermont, Massachusetts, or New Hampshire designated natural areas within the Turners Falls and Northfield Mountain Projects' boundaries.

The Licensee has granted permission to others for non-Project uses of Project lands in accordance with the provisions of the Turners Falls and Northfield Projects' licenses. These non-Project uses include uses of Project lands and waters for a parking area, the Conte Fish Lab, a fire pond, a privately owned boat club, private camps, landscaping activities, agricultural uses, communications antennas, docks, a NPDES discharge, and water withdrawals.

Need for Additional Information:

FirstLight will continue to make land management decisions regarding the use of lands within the Projects. In order to guide in decision making for future use of lands within the Projects' boundaries, FirstLight requires updated land use information regarding the current uses of Project lands and of lands within 200 feet of the Projects' boundaries. This information can then be used to determine appropriate land use designations for lands within the Projects' boundaries. The information would be readily available via GIS mapping and can be continually updated as information changes.

Project Nexus (18 CFR § 5.11(d)(4))

Operation of the Turners Falls Project and the Northfield Mountain Project may have the potential to affect land use within the Projects' boundaries.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Literature and Aerial Photography Review**

FirstLight proposes to review existing land use controls, because land use controls may impact how land is currently being used. Information reviewed will include local plans, ordinances, statutes, policies, and guidelines that may affect use and/or management of Project lands, and the results of resource studies conducted as part of the relicensing process. Using aerial photography, FirstLight will also identify land uses and land use controls on lands abutting the Projects up to 200 feet beyond the Projects' boundaries. Identification of uses of lands within 200 feet of the Projects' boundaries will allow for appropriate designation of lands within the Projects taking into consideration abutting property use.

Task 2: Development and Application of Land Use Designations

FirstLight will use the results of the literature review and the results of the identification of land uses currently occurring within the Projects' boundaries and on adjacent lands to develop appropriate land use designations for lands within the Projects' boundaries. Once land use designations are defined, FirstLight will propose the application of the appropriate designation to lands within the Turners Falls Project and Northfield Mountain Project boundaries.

Task 3: Map and Summary Development

FirstLight will prepare maps and a summary of the results of the inventory. The summary will include the proposed land use designations and definitions, along with the percentage of Project lands in each designation.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort is adequate to obtain baseline information on the existing land uses and land use controls within the Project boundaries and on abutting lands up to 200 feet from the Project boundaries. The estimated cost for this inventory is approximately \$15,000-20,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The *Land Use Inventory* will be initiated in 2014 but because the *Inventory* depends in part on the results of other resources studies proposed herein, the *Inventory* will be completed in 2015

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.6.6 Assessment of Effects of Project Operation on Recreation and Land Use**General Description of Proposed Study**

FirstLight originally proposed this study in the PAD. The study plans to use the information derived from the studies set forth in the Recreation Use/User Contact Survey and the Recreation Facilities Inventory and Assessment to assess the potential impact of continuing operation and maintenance of the Projects on recreation and land use.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

The objective of this assessment is to determine if the operation of the Turners Falls Project and the Northfield Mountain Project has an effect on the recreation facilities or land use within either Project.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreational opportunities associated with the operation of the Turners Falls and Northfield Mountains Projects.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))**Existing Information:**

There are 20 formal recreation facilities located within the Turners Falls and Northfield Mountain Projects' boundary. Section 4.8 of the PAD provided information regarding recreation resources within the Projects and surrounding areas. These facilities provide a variety of amenities, including but not limited to boat ramps, camp sites, picnic tables, benches, trails, and interpretive displays.

Need for Additional Information:

FirstLight will need to review the proposed studies, once completed, to determine if there are effects on the existing public recreation sites or on land use within either Project from Project operations.

Project Nexus (18 CFR § 5.11(d)(4))

The objective of this assessment is to determine if the operation of the Turners Falls Project and the Northfield Mountain Project has an effect on the recreation facilities or land use within either Project.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1: Data Compilation**

FirstLight will review the information derived from the studies set forth in the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)), the *Recreation Facilities Inventory and Assessment* ([Study No. 3.6.2](#)), the *Whitewater Boating Evaluation* ([Study No. 3.6.3](#)), the *Assessment of Day Use and Overnight Facilities Associated with Non-Motorized Boats* ([Study No. 3.6.4](#)), and the *Recreation Study at Northfield Mountain, including Assessment of Sufficiency of Trails for Shared Use* ([Study No. 3.6.7](#)) to assess the

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

potential impact of continuing operation and maintenance of the Projects' on recreation. FirstLight will also review historic and existing water level fluctuation information.

Task 2: Data Analysis

FirstLight will compare the information reviewed in Task 1 to determine if there are access issues resulting from water level fluctuations. This will include analyzing inventory data and comparing it to water elevation data on the dates of the surveys. In addition, FirstLight has proposed to develop a hydraulic model of the Turners Falls Impoundment, bypass reach and of the Connecticut River below Cabot Station down to Holyoke Dam ([Study 3.2.2](#) *Hydraulic Study of Turners Falls Impoundment, Bypass Reach and below Cabot Station*), which will also be used in the assessment of impacts to recreational access from water level fluctuations.

Task 3: Report Development

FirstLight will prepare a report with the results of the study, including a determination if there are access issues due to fluctuating water levels and where they may be occurring.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the assessment as proposed above is sufficient to determine if the operation of the Projects has an effect on the recreation facilities or land use within the Project. It is estimated that this assessment will cost approximately \$10,000-12,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The *Assessment of Effects of Project Operations on Recreation and Land Use* will be initiated in 2014 but because the *Assessment* depends in part upon the results of other studies, it will be completed in 2015.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.6.7 Recreation Study at Northfield Mountain, including Assessment of Sufficiency of Trails for Shared Use**General Description of Proposed Study**

A number of stakeholders requested this study including: NPS, AMC, VRC, FCRP, and Ms. Krug. This study is designed to determine the number of existing recreation facilities, the number and types of amenities available at each facility and the overall condition of the facilities associated with the Northfield Mountain Project. This will include a review of the trail system and climbing ledges located within the Northfield Mountain Project boundary.

NPS/AMC et al request that the study of the Northfield Project recreation facilities include a survey that seeks to determine what discourages the public from using the facilities. FirstLight proposes to use the contact and mail surveys conducted as part of the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)) to seek out what improvements may be needed. As set forth, however, in the *Assessment of Day Use and Overnight Facilities Associated with Non-Motorized Boating* ([StudyNo. 3.6.4](#)), FirstLight does not propose to conduct a survey of non-users or displaced users because such a survey will not yield reliable or meaningful information in consideration of the level of effort required.

Ms. Krug requests that FirstLight evaluate trail networks in Franklin County to determine the need for additional trails and to conduct a site visit to some of these trails. This was not adopted because these trails are located outside of the Project area. FirstLight is proposing to gather information regarding the trail needs for mountain biking as part of the user contact survey proposed in *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)).

NPS requests that FirstLight evaluate its expenditures over the term of the current license in support of the facility, its promotion, and usage and extrapolate in current dollars, what would be necessary to bring the facility up to the quality and level of use that applicable FERC regulation prescribe. Past expenditure information is available on the FERC Form 80 and has not been included as part of this study. As part of its license application, FirstLight will provide estimates for any proposed recreational improvements.

Ms. Krug asks for online user surveys to talk to mountain bike groups regarding the needs of mountain bicyclists and assess interest in opportunities at Northfield Mountain. Internet surveys are not appropriate for quantitative analysis because they are not representative of the general recreational user population and do not provide reliable results. FirstLight proposes to use the results of the surveys proposed in the *Recreation Use/User Contact Survey* ([Study No. 3.6.1](#)) to seek out what improvements may be needed.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to compile existing data and develop additional information to support a new FERC license application for continued future operation of the Project.

The objectives of this study are as follows:

- Determine whether the Northfield Mountain Tour and Trail Center has met recreation needs and if improvements or additions are necessary at the Center with a consideration of potential needs over the course of the 30 to 50 year new license; and
- Identify uses taking place on the current trail system and whether the current trail system is suitable and adequate for sustaining those uses, including evaluating the condition of existing trails e.g., erosion, drainage, width, slope, or obstacles.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

The resource management goals are to enhance the recreation opportunities associated with the operation of the Northfield Mountain Project.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))Existing Information:

The Northfield Mountain Tour and Trail Center, Northfield Mountain Trail System and Northfield Mountain Mountaintop Observation Area provide numerous recreation opportunities within the Northfield Mountain Project boundary. Although they are not formal recreation facilities, Rose Ledge and Farley Ledge provide climbing opportunities to the public. The three formal recreation facilities are described in detail below.

Northfield Mountain Tour and Trail Center: This site, which is also known as the Visitor Center, is located within the Northfield Mountain Project, off Millers Falls Road (Rt. 63) in Northfield, MA. The Center is owned and managed by the Licensee and is available for day use activities. Available opportunities include viewing interpretive displays, picnicking, and educational programs. The Center has restrooms, cross-country ski rental equipment, and parking. It is open for year-round recreational and educational use.

Northfield Mountain Trail System: The trail system is located at the Northfield Mountain Project, off Millers Falls Road (Rt. 63) in Northfield, MA. Over twenty-six miles of trail are available for hiking, biking, trail running, horseback riding, snowshoeing, and cross-country skiing. Climbers currently utilize a portion of the trail system to access Rose Ledge.

Northfield Mountain Mountaintop Observation Area: This site is located adjacent to the Northfield Mountain Project upper reservoir. The Observation Deck is owned and managed by the Licensee and is accessible by using the trail system.

Project Nexus (18 CFR § 5.11(d)(4))

FERC regulations require that the license application include a statement of the existing recreation measures or facilities to be continued or maintained and the new measures or facilities proposed by the applicant for the purpose of creating, preserving, or enhancing recreational opportunities at the Projects and in their vicinities, and for the purpose of ensuring the safety of the public in its use of Project lands and waters. In addition, recreation is a recognized project purpose at FERC-licensed projects under section 10(a) of the FPA.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))Task 1: Review of Existing Information

The Licensee proposes to use data collected as part of the *Recreation Use and User Contact Survey* ([Study No. 3.6.1](#)) to identify opinions of current recreation users of the Northfield Mountain recreation facilities. Prior to conducting field work associated with this study, a review of proposed trails, existing aeriels and property ownership will be conducted.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing hiking and biking trail information for the Northfield Mountain area will be reviewed, as well as best management practices set forth by the International Mountain Bicycling Association, the USFS Trail Classifications, and the MA Department of Conservation & Recreation's Trail Guidelines and Best Practices standards.

Task 2: Field Work

The Licensee will conduct a field review of the current trail system, climbing sites, and the existing portion of the New England National Scenic Trail. This will include locating the sites with a GPS, if the information does not currently exist; photographing and recording the current amenities and conditions of the sites; and determining if there is a need for improvement.

Task 3: Desktop Analysis

A desktop analysis will be conducted to compare field data, survey data, and existing information. The analysis will determine if the current facilities are meeting the existing recreation needs at Northfield Mountain and provide a list of potential improvements that could be completed if the need arises over the course of the license.

Task 4: Report Development

The information collected will be compiled within a written report.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

FirstLight believes that the proposed level of effort is sufficient to obtain information on recreational facilities and amenities at Northfield Mountain, within the Northfield Mountain Project boundary. The estimated cost for the study outlined in this plan is approximately \$20,000-\$25,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The *Recreation Study at Northfield Mountain, including Assessment of Need for Shared-Use Trails* will be conducted in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.7 Cultural Resources*3.7.1 Phase 1A Archaeological Survey***General Description of Proposed Study**

In its PAD, FirstLight proposed to conduct a Phase 1A archaeological survey. FERC and the Town of Montague have requested assessments of archaeological resources. The purpose of the Phase 1A archaeological survey is to identify known archaeological sites within the Turners Falls and Northfield Mountain Projects' APE that potentially may be eligible for inclusion in the National Register of Historic Places (NRHP) and to assess possible effects from the Projects' operations on those resources.

The area of investigation will include the FERC-defined APE as identified in the PAD, which includes the Projects' boundaries and any construction, recreational, or known locations effected by project operation outside of the Projects' boundaries. The Project APE is further defined by FERC as: "the lands enclosed by the Projects' boundary and lands or properties outside of the Project's boundaries where project construction and operation or project-related recreational development or other enhancements may cause changes in the character or use of historic properties, if any historic properties exist." The Massachusetts, Vermont, and New Hampshire SHPOs will be consulted for concurrence with or refinement of this definition. A detailed map of the APE will be prepared and included in the Study Report.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to assist FERC in meeting its compliance requirements under Section 106 of the NHPA, as amended, by determining if licensing of the Project will have an adverse effect on historic properties.

The objective of the study is to identify known cultural resources listed in or eligible for listing in the NRHP and to identify and assess any potential adverse effects to historic properties from the continuing operation and maintenance of the Projects.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

Section 106 of the National Historic Preservation Act (1966) requires that federal agencies, licensees, and those receiving federal assistance take into account the effects of proposed undertakings on any resource that is listed on or is eligible for the NRHP. As the lead agency, FERC is responsible for fulfilling the requirements of Section 106 in its decision to issue a new license to the Projects.

As stipulated by the regulations that implement Section 106 (36 CFR 800), the Massachusetts, Vermont, and New Hampshire SHPOs represent the interests of their respective States and their citizens, and advise and assist FERC in determining the significance of cultural resources within the APE. FirstLight proposes consulting closely with the SHPOs in the development of the survey methodology, identification of existing cultural resources and effects, establishment of its APE, and development of a Programmatic Agreement (PA) and HPMP, if needed.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

Information contained in the PAD indicates that Native Americans have occupied the Connecticut River Valley as early as 14,000 years before the present day. Archaeological sites dating from the *Paleoindian*

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

(before 8000 BC), *Archaic* (8000 BC – 1000 BC), and *Woodland* (1000 BC – AD 1600) periods, as well as the early Euro-American exploration, settlement, and industrial periods, may exist on lands bordering the Connecticut River. The Riverside Archaeological District in the Towns of Gill and Greenfield was listed in the NRHP in 1975 in recognition of significant archaeological remains known to exist in the Turners Falls vicinity. European settlement in the Connecticut River basin in what was to later become Northfield Township and the Town of Gill occurred as early as 1672. During King Phillip's War in 1676, Peskeopscut (Turners Falls) was the site of a military encounter between colonial forces under Captain William Turner and Native Americans. Following the American Revolution, transportation improvements included construction of the Upper Locks and Canal (1792-98) from Turners Falls to Montague. After the Civil War, Turners Falls developed as an important center of manufacturing with the establishment of the Turners Falls Company in the early 1870s. In the 1890s, Turners Falls continued to expand with construction of a new paper mill, shoe factory, and leather manufacturers.

To date, there have been no comprehensive, professional archaeological surveys of the Project APE to identify such resources. FirstLight therefore proposes to conduct the Phase IA archaeological survey to identify potential NRHP-eligible archaeological resources in the Projects' APE and provide information to assess potential adverse effects to such resources.

Project Nexus (18 CFR § 5.11(d)(4))

The proposed cultural resources study will provide information on known archaeological sites located within the Projects' APE. The resulting technical reports will provide information on which resources are potentially eligible for inclusion in the NRHP and what potential adverse effects to these historic properties would be created by the continued operation of the Project. Once the potential adverse effects are determined, the information that is developed during the course of the study may be used as the basis for preparing an HPMP. Guiding the Licensee's actions relating to Section 106 during the term of the new license, an HPMP would discuss how to avoid potential adverse effects or how they would be mitigated. A final HPMP would be filed with the license application.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1 – Meeting with the Massachusetts, Vermont, and New Hampshire SHPOs**

FirstLight will consult with the Massachusetts, Vermont, and New Hampshire SHPOs to reach concurrence with respect to the precise APE for the Projects, the development of a sensitivity model, and archaeological field reconnaissance methodology.

Task 2 – Background Research

FirstLight proposes to examine archaeological site files, cultural resources reports, and archives located at the Massachusetts, Vermont, and New Hampshire SHPOs and other local and regional repositories, such as the Great Falls Discovery Center in Turners Falls and the Pocumtuck Valley Memorial Association in Deerfield. The purpose of this work is to examine relevant sources that may contain historical and archaeological information on the two Project areas in order to develop prehistoric and historic contexts and an archaeological sensitivity model. As part of this study, FirstLight will endeavor to obtain background information from local historians, researchers, and other persons knowledgeable of the cultural history of the two Project areas.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 3 – Development of a Sensitivity Model

FirstLight will develop a sensitivity model, based on its consultation with the SHPOs and background research to identify areas within the APE that are likely to contain archaeological resources. FirstLight will obtain the SHPOs concurrence with the sensitivity model.

Task 4 – Field Reconnaissance

FirstLight also proposes to conduct archaeological field reconnaissance of the Turners Falls Project and Northfield Mountain Project areas to confirm the sensitivity models and eliminate areas from further study as warranted. The field reconnaissance will consist of visual examination of selected portions of the Project areas, focusing primarily on landforms that have the greatest potential to contain archaeological resources, and as well as confirming areas of disturbance, steep slope, and wetlands, which would have little potential to contain archaeological resources. A limited number of soil cores may be taken to confirm soil characteristics and/or ground disturbances; it is anticipated that no other ground disturbance will be required for this study. The methods to achieve the goals of this study will be conducted in consultation with the SHPOs following their professional standards and guidelines. FirstLight will employ a professionally qualified archaeologist who meets the *Secretary of the Interior's Standards* to conduct the cultural resources study.

Task 5 – Report Development

FirstLight will develop a report that contains a record of its consultation with the SHPOs, a summary of background research, a description of the sensitivity model, results of Phase 1A reconnaissance, maps of the APE, and recommendations to conduct, if necessary, a Phase IB archaeological survey depending on the results of the study and in consultation with the SHPOs.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The estimated cost for the Phase IA cultural resources survey is between \$55,000 and \$65,000. FirstLight believes that the proposed level of effort is adequate to obtain needed information on historic and prehistoric cultural resources within the Projects' APE and to determine the need for more intensive surveys.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight's PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The *Phase IA Archaeological Survey* will be conducted in 2014.

Study reporting will be conducted in accordance with FirstLight's Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC's SD1

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

*3.7.2 Reconnaissance-Level Historic Structures Survey***General Description of Proposed Study**

In its PAD, FirstLight proposed to conduct a Historic Structures Survey. FERC also noted that FirstLight had proposed such a survey. The purpose of the reconnaissance-level historic structures survey is to identify historic resources within the Turners Falls and Northfield Mountain Projects' APE that are listed in or may be eligible for listing in the NRHP and to assess possible effects from the Projects' operations on those resources. This will be accomplished through SHPO consultation, site file research and literature review, and field studies. A reconnaissance-level historic structures survey will be conducted to gather information on known historic architectural resources in the Projects' APE and to identify buildings, structures, objects, sites and districts for possible further intensive-level survey. Existing information will be collected from records maintained at the Massachusetts, Vermont, and New Hampshire SHPOs, state and local libraries and historical societies, the Library of Congress, and the National Register in Washington, DC.

The area of investigation will include the FERC-defined APE as identified in the PAD, which includes the Projects' boundaries and any construction, recreational, or known locations affected by project operation outside of the Projects' boundaries. The Project APE is further defined by FERC as: "the lands enclosed by the Projects' boundary and lands or properties outside of the Project's boundaries where project construction and operation or project-related recreational development or other enhancements may cause changes in the character or use of historic properties, if any historic properties exist." The Massachusetts, Vermont, and New Hampshire SHPOs will be consulted for concurrence with or refinement of this definition. A detailed map of the APE will be prepared and included in the Study Report.

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goal of the study is to assist FERC in meeting its compliance requirements under Section 106 of the NHPA, as amended, by determining if licensing of the Project will have an adverse effect on historic properties.

The objective of the study is to identify cultural resources listed in or eligible for listing in the NRHP. If it is confirmed that historic properties are present, FirstLight will then move forward to identify and assess any potential adverse effects to historic properties from the continuing operation and maintenance of the Project.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

Section 106 of the National Historic Preservation Act (1966) requires that federal agencies, licensees, and those receiving federal assistance take into account the effects of proposed undertakings on any resource that is listed on or is eligible for the NRHP. As the lead agency, FERC is responsible for fulfilling the requirements of Section 106 in its decision to issue a new license to the Projects.

As stipulated by the regulations that implement Section 106 (36 CFR 800), the Massachusetts, Vermont, and New Hampshire SHPOs represent the interests of their respective States and their citizens, and advise and assist FERC in determining the significance of cultural resources within the APE. FirstLight proposes consulting closely with the SHPOs in the development of the survey methodology, identification of existing cultural resources and effects, establishment of its APE, and development of a PA and HPMP, if needed.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

European settlement in the Connecticut River basin in what was to later become Northfield Township and the Town of Gill occurred as early as 1672. During King Phillip's War in 1676, Peskeopscut (Turners Falls) was the site of a military encounter between colonial forces under Captain William Turner and Native Americans. Following the American Revolution, transportation improvements included construction of the Upper Locks and Canal (1792-98) from Turners Falls to Montague. After the Civil War, Turners Falls developed as an important center of manufacturing with the establishment of the Turners Falls Company in the early 1870s. In the 1890s, Turners Falls continued to expand with construction of a new paper mill, shoe factory, and leather manufacturers.

The Turners Falls Historic District, containing residential, commercial, and industrial buildings and structures associated with the nineteenth-century industrial history of Turners Falls, and including historic resources located within the Project boundaries, was listed in the National Register in 1982. Because there have been no comprehensive architectural surveys conducted within the Projects' APE, there is the potential for other NRHP-eligible resources located within the Projects' boundaries in Massachusetts, Vermont, and New Hampshire. These resources will be identified during reconnaissance- and intensive – level architectural surveys proposed by FirstLight.

Project Nexus (18 CFR § 5.11(d)(4))

The proposed reconnaissance-level historic structures survey will provide information on known (previously identified) historic resources within the Projects' APE and the location of resources that may be recommended for further intensive survey. Following further consultation with the appropriate SHPOs, the intensive-level survey, if any, will seek to provide information on resources potentially eligible for NRHP listing. Once NRHP eligibility determinations have been obtained for the intensively surveyed resources, potential effects to these historic properties by continued Project operations will be assessed. Information developed during the course of the intensive survey will be used as the basis for preparing an HPMP. Guiding the Licensee's actions relating to Section 106 during the term of the new license, the HPMP will discuss how to avoid potential adverse effects or how they will be mitigated. The final HPMP will be filed with the license application.

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))**Task 1 – Meeting with the Massachusetts, Vermont, and New Hampshire SHPOs**

FirstLight will consult with the Massachusetts, Vermont, and New Hampshire SHPOs to reach concurrence with respect to the precise APE for the Projects, the development of historic contexts, and field reconnaissance methodology.

Task 2 – Background Research

FirstLight proposes to examine architectural site files (not available on-line), cultural resources reports, National Register nominations, historic maps and atlases, and building records located at the Massachusetts, Vermont, and New Hampshire SHPOs and other research repositories, such as the Great Falls Discovery Center in Turners Falls, the Pocomtuck Valley Memorial Association in Deerfield, local libraries and historical societies, and at FirstLight's offices.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 3 – Development of Historic Contexts

FirstLight will use the results of the background research to develop historic contexts to guide the field reconnaissance and will consult with the SHPOs regarding the historic contexts.

Task 4 – Field Reconnaissance

FirstLight also proposes to conduct field reconnaissance (“windshield survey”) of the Turners Falls Project and Northfield Mountain Project APE to identify architectural resources (buildings, structures, objects, and districts) 50 years or older. Survey methods will follow the relevant SHPO professional standards and guidelines. FirstLight will employ professionally qualified architectural historians, who meet the *Secretary of the Interior’s Standards*.

Task 5 – Report Development

FirstLight will develop a report that contains a record of its consultation with the SHPOs, a summary of the background research, a description of the historic contexts, results of the windshield survey, maps of the APE, and recommendations to conduct an intensive-level architectural survey, depending on the results of the reconnaissance-level survey and after consultation with the SHPOs.

Level of Effort and Cost (18 CFR § 5.11(d)(6))

The estimated costs for the background research and windshield survey to identify 50-year-and-older resources within the Projects’ APE are approximately \$30,000 to \$40,000. Costs associated with the intensive-level survey and assessment of effects will be developed following consultation with the SHPOs on the results of the reconnaissance-level survey. FirstLight believes that the proposed level of effort is adequate to obtain initial information on historic resources within the Projects’ APE.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

In accordance with 18 CFR § 5.15(c), a Study Plan Meeting will be held on May 14, 2013. The purpose of the Study Plan Meeting will be to informally resolve any outstanding issues with respect to FirstLight’s PSP and the study requests filed by stakeholders, and to clarify the PSP and any information gathering and study requests. The *Reconnaissance-Level Historic Structures Survey* will be conducted in 2014.

Study reporting will be conducted in accordance with FirstLight’s Process Plan and Schedule (18 CFR § 5.6(d)(1)), as provided in the PAD, and the FERC’s SD1.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

3.8 Developmental Resources**3.8.1 *Evaluate the Impact of Current and Potential Future Modes of Operation on Flow, Water Elevation and Hydropower Generation*****General Description of Proposed Study**

A simulation model of the Connecticut River Basin will be used to evaluate the impacts of current and potential alternative modes of operation in the Project area on the timing and magnitude of river flows. Output from the model--- specifically flow data---will be used in other studies to evaluate the impact of current and potential alternative modes of operation on water surface elevations (hydraulic model) and aquatic habitat.

The Connecticut River Joint Commission (CRJC) requested a Connecticut River basin-wide stormwater model. The goals and objectives of the CRJC's study request refer to stormwater; however, the proposed methodology refers to a simulation model as described further below. FirstLight contacted the CRJC to clarify whether they are seeking a basinwide stormwater runoff model or a simulation; it appears they are seeking the latter (simulation model).

Study Goals and Objectives (18 CFR § 5.11(d)(1))

The goals and objective of this study are to:

- To develop a baseline model of the Connecticut River Basin---specifically the reach from TransCanada's Wilder Project to the Holyoke Project-- which includes the following hydropower facilities: TransCanada's Wilder, Bellows Falls, and Vernon Hydroelectric Projects, FirstLight's, Turners Falls Hydroelectric Project and Northfield Mountain Project and Holyoke Gas and Electric's Holyoke Hydroelectric Project.
- The model will be used to determine the impact on hydropower generation and economics due to potential alternative modes of operation. Potential alternative modes of operation could include minimum flows in the bypass reach, changes in the Turners Falls Impoundment fluctuations, changes in operation of the Turners Falls Project relative to peaking operations, etc.
- Flow data generated from the model will be used to inform other studies, notably the hydraulic model and instream flow study.

Resource Management Goals of Agencies/Tribes with Jurisdiction over Resource (18 CFR § 5.11(d)(2))

FirstLight proposed to develop an operations model of the Wilder, Bellows Falls, Vernon, Northfield Mountain, Turners Falls and the Holyoke hydropower facilities in the PAD.

The FRCOG Study Request No. 6 is entitled "*Model River Flow and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Facilities*". FRCOG is requesting the development of a river model to evaluate the impact of Project operations on flows and water levels in the Project area.

The FRCOG Study Request No. 7 is entitled "*Develop a Comprehensive and Predictive Model of the Electric Generation System Consisting of Five Generation Projects along the Connecticut River to study the Impact and Feasibility of Various changes in Operations on Environmental Resources*". The FRCOG

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

notes that the study objective is to determine whether operating the system (Wilder, Bellows Falls, Vernon, Northfield Mountain, and Turners Falls) as a whole under a single set of operation parameters could serve to mitigate the environmental impacts of current operations.

FirstLight believes that both of FRCOG's study requests can be addressed in the proposed simulation model of the Connecticut River Basin.

Existing Information and Need for Additional Information (18 CFR § 5.11(d)(3))

The Nature Conservancy (TNC), USGS, USACE, and University of Massachusetts (UMass) at Amherst ("Project Partners") have developed a simulation and optimization model of the Connecticut River Basin. Software used for the simulation model is the USACE Hydrologic Engineering Center Reservoir Simulation model or HEC-ResSim. The optimization model was developed using software called LINGO. FirstLight has been working with Project Partners and provided them with engineering and operations data on the FirstLight facilities to enter into the HEC-ResSim model. Project Partners have provided FirstLight with the HEC-ResSim model of the Connecticut River Basin. HEC-ResSim is a simulation model and operates based on a set rules and constraints set by the modeler. The Connecticut River simulation model was developed on a daily time step for the period 1960 to 2003.

Daily inflow for the model was developed by the USGS using its Connecticut River Unimpacted Streamflow Estimation (CRUISE) model. FirstLight is using the same daily inflow data, but will convert it to an hourly time step using straight line interpolation.

Project Nexus (18 CFR § 5.11(d)(4))

Potential changes in project operations at the three TransCanada Projects and FirstLight Projects will have a direct impact on the generation and economic viability at the Turners Falls Hydropower Project and the Northfield Mountain Project. Output from the model, most notably time varying flows, will be used in other studies (hydraulic model, instream flows study).

Methodology (18 CFR § 5.11(b)(1), (d)(5)-(6))

FirstLight proposes to conduct the following tasks using the HEC-ResSim simulation model.

Task 1. Modify Model

The Project Partner model provided to FirstLight is on a daily time step. FirstLight will modify the model such that daily unregulated flow data is converted to an hourly time using straight line interpolation. In the end, an hourly time step model will be developed for the period 1960 to 2003. The model provided by Project Partners will be refined further to better simulate the timing of pumping and generating cycles at Northfield Mountain and the use of reservoir storage in the upper and lower reservoirs. Other modifications to the model will include: a) properly simulating the timing and magnitude of fish ladder flows, attraction flows, bypass flows, and b) properly simulating the use of upper and lower reservoir storage.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 2: Calibration

The model will be calibrated to flow and generation using observed data for a recent year such as 2002 or 2003²⁶. Relative to flow, the model predicted daily (and hourly) hydrograph will be compared against the daily (and hourly) hourly hydrograph at the USGS Gage in Montague City, MA, located below Cabot Station. Comparing model predicted flow and observed flow at the gage will indicate if the model is reasonably matching the timing and magnitude of streamflow. In addition to flow, total monthly generation predicted by the model will be compared to the observed monthly generation at the three TransCanada Projects, Northfield Mountain Project and Turners Falls Project. It will be important to review the FirstLight log sheets to determine if there were any station or individual unit outages as the model will not account for outages. The model would over-predict generation if there is a prolonged outage. Based on flow and generation findings, some fine tuning of the HEC-ResSim model may be needed to match observed conditions.

Note that the year selected for calibration (2002 or 2003) may not represent the current project equipment. For example, say in 2007 the turbines at Cabot Station were upgraded meaning that the turbine efficiency would be improved over the turbines in place in 2002 or 2003. For calibration purposes, FirstLight will rely on the equipment installed during the years selected for calibration.

Task 3. Establish Baseline Model

Once the model is calibrated, it will be updated to reflect today's equipment and operating conditions and is termed the baseline model. Output from the baseline model including generation, flows and water levels will be used as a basis of comparison to any other model runs.

Task 4. Production Runs

A production run is considered any change made to the baseline model. The HEC-ResSim model allows for simulating alternative modes of operation based on a set of constraints and rules. Alternative modes of operation that can be simulated in the HEC-ResSim model include:

- Changes in the allowable water level fluctuation in a given reservoir;
- Changes in the magnitude and timing of bypass flows;
- Changing the magnitude and timing of fishway flows and attraction flows;
- Changes in the timing and magnitude of hydropower releases;
- Placing maximum discharge constraints on hydropower releases
- Changing the hydraulic capacity at a given facility.

If a stakeholder seeks an alternative mode of operation, such as maintaining bypass flows, the impact on generation, reservoir water levels and flows can be compared between this "Production Run" and the baseline model.

²⁶ The inflow data for the model provided to us by TNC terminated in 2003.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Task 5. Use of Model Output for other Uses

Output from the HEC-ResSim model will be used to inform other studies. For example, [Study No. 3.3.1 Conduct Instream Flow Habitat Assessments in the Bypass Reach and below Cabot Station](#) will include a habitat time series analysis. The hourly discharge hydrograph from the model at Montague City will be matched with the habitat versus flow relationship developed as part of the [Study No. 3.3.1](#) to generate hourly varying habitat.

Task 6. Report

A report will be developed documenting the model inputs (engineering data, physical data, and flow data), and results from the calibration model, baseline model and Production Runs

Level of Effort and Cost (18 CFR § 5.11(d)(6))

Because FirstLight is using the HEC-ResSim model initially developed by the Project Partners, the level of effort is less than if developing the model from scratch. However, the model provided to FirstLight will still require significant updates to reflecting the intra-day operation and dispatch of the project, which cannot be simulated in a daily time-step model. Model calibration, establishment of a baseline model, development and simulation of Production Runs and a report are needed. The estimated cost of the modeling effort is on the order of \$100,000 to \$125,000.

Study Schedule (18 CFR § 5.11(b)(2) and (c))

Development of the simulation model does not require the collection of any field data. As such, FirstLight plans on completing model calibration and establishing a baseline model in 2013. Additional modeling of will be conducted in 2014 and 2015 as field studies are completed that will better inform potential Production Runs. For example after the instream flow study is complete, it will be used to inform potential bypass flows, which will be simulated in the model to evaluate impacts on generation.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.0 STUDIES NOT INCLUDED IN THE PSP

The following section describes the studies not included in FirstLight's PSP.

4.1 Geology and Soils*4.1.1 Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage Operations*

The following groups requested the same study: FRCOG, CRWC, FCD, Town of Gill, and LCCLC. In addition, NHDES and VANR requested a similar study titled *Vernon and Turners Falls Hydroelectric Projects: Shoreline and downstream erosion from water level fluctuation in the impoundment and downstream from peaking operations in New Hampshire*.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

Proponents state that the study objectives would be to: (1) calculate the total volume of eroded material, calculate resulting nutrient loading of eroded material, and document and describe the three dimensional changes to the bank, including lateral bank recession, changes to bank slope, and the presence and subsequent inundation of pre-project beaches and shoreline since the Turners Falls Dam was raised and the Northfield Mountain Project came on-line; (2) document and describe the changes to banks upstream and downstream of riverbank restoration projects, including bank recession; and (3) identify the changes that have occurred to bed substrate as a result of fine grain material being eroded from the banks and being deposited on the channel bed.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

FRCOG, CRWC, FCD, Town of Gill, and LCCLC are not resource agencies.

Public Interest Considerations (18 CFR § 5.9(b)(3))

Proponents state that fish and wildlife are important public resources and as such it is in the public interest to maintain high quality habitat for migratory diadromous fish. Further, the proponents indicate that eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turners Falls Impoundment, the bypass reach, and downstream of Turners Falls Dam reduced the quality of habitat for these species.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

Proponents note several existing studies, including those contained in the PAD relative to Turners Falls Impoundment erosion, including past FRR's, Field Geology Services' 2007 fluvial geomorphic assessment of the Turners Falls Impoundment, and the 2012 investigations conducted by Simons and Associates. The proponents note that historic aerial photography of the Turners Falls Impoundment from 1929 aerials should be gathered and analyzed.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

Proponents state that the construction of the Northfield Mountain Project was contingent upon the raising the Turners Falls Dam crest elevation by 5.9 feet which in turn has lead to water level fluctuations and increased boat activity. As a result, the proponents' state that erosion caused or contributed to the Northfield Mountain Project operation can negatively affect spawning, rearing and migratory habitat for trust species and the endangered shortnose sturgeon.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

Proponents' methodology includes:

1. Determine the net soil loss in cubic yards between 1970 and the present; a density estimate of the eroded material should also be provided. Provide an analysis of where the greatest loss has occurred, location of proximity to the tailrace, soil type, riparian land use, and vegetative cover in that area. Calculate nutrient loadings (nitrogen and phosphorus compounds) to the river system based on soil loss;
2. Obtain copies of the original survey plans for the project, and complete a new survey using the same landmarks used previously. Use pre-operation aerial photos and current aerial photos to complete a 10-foot topographic map of the section of river between Turners Falls Dam and Vernon Dam and the 200-foot buffer regulated under the Massachusetts Rivers Protection Act. Create a single map showing areas of erosion and deposition, and also overlay the Field report's hydraulic modeling analysis of the river channel;
3. With respect to the January 22, 2013 submittal from FirstLight to FERC regarding its long term monitoring transects in the Turners Fall impoundment, we ask that any data errors (as discussed in Field, 2007) and problems that have occurred over the years at each site be mentioned. We also ask that an analysis for each cross section extending to the top of the bank and including a portion of the floodplain be provided;
4. Take the information presented in Figure 4.2.3-1 "Soils in the vicinity of Turners Falls and Northfield Mountain projects" in the PAD and convert from 63 categories to just a few that are defined in a key that will allow readers to understand which soils are easily erodible, which aren't, and where there is bedrock along the banks;
5. Complete detailed surficial mapping (topographic map or LIDAR) to identify the various geomorphic surfaces, height of benches/terraces above the river level, and types of sediments underlying the surfaces;
6. An analysis on the degree to which boat wakes increase that fluctuation range;
7. Determine erosion and riverbank failure process at identified sites;
8. Determine the effects of erosion on other resources; and
9. Develop a Shoreline Management Plan

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

Proponents' state: *"The level of effort to compile existing information and to make the data available in a map and searching for existing bed substrate material data should not take more than a few days. The level of effort for the bed sampling work will vary based upon how much historic information exists. Much of the effort of this study request is essentially office work that compiles and better presents existing data. While an estimate on the amount of field time required is difficult to make, we estimate that up to two weeks of field work could be required and some of the data collection could be done while other field studies are occurring."*

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight's Rationale for Not Adopting the Proposed Studies

FirstLight does not see the need to conduct historical analysis of soil loss, erosion, nutrient loading, topography, or other geomorphic principles as requested for numerous reasons. First, as FirstLight has explained in many past FERC filings, rivers naturally migrate causing natural bank erosion, especially in the alluvial soils such as those flanking the Turners Falls Impoundment. Erosion could be caused by natural high flows, Project operations, boat wakes, upland management practices and other reasons. Thus, it is unclear why understanding the cubic yards of bank erosion in the impoundment is necessary. Second, in its *Guide to Understanding and Applying the Integrated Licensing Process Study Criteria*, FERC reiterates that FERC uses current conditions as its baseline for evaluating project effects and alternatives and that this consists of the environment as it exists at the time of licensing.²⁷ FirstLight believes that the request is seeking a comparison to pre-raising-of-the-dam conditions. Finally, it is unclear how the requested data would inform potential PME measures. Additionally, FirstLight is not proposing to conduct topographic mapping or LiDAR along the 20-mile long Turners Falls Impoundment as existing topography is available from other sources and it is expensive. FirstLight will rely on the existing upland mapping obtained from USGS National Map Viewer- more specifically, the USGS 10 meter digital elevation model (DEM).

Relative to the long term monitoring transects as noted in a footnote in Field, 2007: *FirstLight has independently reviewed the 21 cross sections and checked the over 400 individual data sets and determined that a small percentage of them are suspect and should not be used for analysis. Therefore, it appears the problem is not extensive and it is unlikely the results of the analysis will change. FirstLight is working to resolve the matter.* For future monitoring, the cross sections will be monumented to allow for repeated measurements and they will extend into the floodplain.

FirstLight is proposing in [Study No. 3.1.2 Northfield Mountain/Turners Falls Project Operations Impact on Sediment Transport](#) to: (1) develop soils maps as a GIS overlay for use in field investigations, reducing the soil groupings to common types- likely ten, to more easily identify easily erodible soils as requested; (2) evaluate surficial mapping in locations where active or recent streambank erosion is occurring. Fixed recoverable cross-sections will be taken only in the areas of erosion; (3) analyze soils (classification, structure, parent material, etc.) at each transect; (4) conduct an analysis of water level fluctuations; and (5) analyze field collected data on boat (July 12-13, 1997 and July 26-27, 2008). In addition, some information on the number of boats will be obtained as part of the recreation studies; however, FirstLight is not proposing to collect the level of detail sought in the study request.

In regard to the NHDES and VANR request, components of the objectives described in Task 7 and 8 are captured in [Study No. 3.1.1 2013 Full River Reconnaissance Study](#) and [Study No. 3.1.2 Northfield Mountain/Turners Falls Project Operations Impact on Sediment Transport](#) therefore FirstLight is not proposing to collect the level of detail sought in the study request. FirstLight is not proposing to develop a Shoreline Management Plan as requested in Task 9.

²⁷ *Guide to Understanding and Applying the Integrated Licensing Process Study Criteria*, at p. 14 (Federal Energy Regulatory Commission, Office of Energy Projects, March, 2012)

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.1.2 Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River.

The following groups requested the same study: FRCOG, CRWC, FCD, Town of Gill, LCCLC, and NHFGD.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

Proponents state that the study objectives would be to: (1) assess hydraulic and sediment dynamics in the Connecticut River from Vernon Dam to Turners Falls Dam, the upper reservoir at Northfield Mountain, and downstream of the Turners Falls Dam; (2) identify management measures to minimize erosion and sedimentation; (3) determine areas of sediment deposition and beach formation in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas, recreational uses and effects on invasive species, if any. Habitat areas include but are not limited to coves (e.g. Barton Cove), back channels, islands, wetland habitats, shorelines, shoals, deep water areas and channels; and (4) identify management measures to mitigate for substrate (habitat) impacts and recreational impacts in sediment-starved areas below the dam and sediment accumulation areas upstream of the dam.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

FRCOG, CRWC, FCD, Town of Gill, and LCCLC are not resource agencies.

NHFGD state that in order to meet the objectives of the federal Clean Water Act, MADEP adopted the Massachusetts Surface Water Quality Standards, 314 CMR 4.00. Additionally NHFGD notes, MADEP has designated the Connecticut River as a Class B river for its entire length in Massachusetts, 314 CMR 4.06(5). Class B rivers are assigned the designated uses of habitat for fish, other aquatic life and wildlife, and for primary and secondary contact recreation, 314 CMR 4.05(3)(b). Class B waters must also have consistently good aesthetic value and meet minimum criteria for numerous water quality indicators to achieve compliance with the standards set forth in the regulations. The anti-degradation provisions of 314 CMR 4.04 require protection of all existing and designated uses of water bodies, and maintenance of the level of water quality needed to protect those uses.

Public Interest Considerations (18 CFR § 5.9(b)(3))

Proponents state that Connecticut River is a valued public resource and that the public has a strong interest in protecting the water quality of the river to maintain its status as a Class B river, as designated by MADEP, 314 CMR 4.06(5).

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

Proponents note that the PAD provides a summary of the work that has been done to characterize streambank conditions of the Turners Falls Impoundment, to understand the causes of erosion, and to identify the most appropriate approaches for bank stabilization. The entities also note the implementation of the *Sediment Management Plan* (revised February 15, 2012) and the *Erosion Control Plan for the Turners Falls Pool of the Connecticut River* (Simons & Associates, Inc. dated June 15, 1999).

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

Proponents state that current water level fluctuations in the Turners Falls Impoundment, combined with proposed increased flow at the Northfield Mountain Project, have resulted/will result in the discharge of large quantities of sediment. Additionally, the proponents assert that sediment from shoreline erosion and

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

riverbank failure is one of the major contributors that negatively affect water quality and habitat by increasing the turbidity and sedimentation, smothering aquatic habitat.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

Proponents' methodology includes:

1. Implementing the Northfield Mountain Pumped Storage Project *Sedimentation Management Plan* over the full range of river flows and pumping/generating cycles. Develop a correlation over the full range of flow conditions between the overall suspended sediment transport through the entire cross section of the river compared to the continuous sampling at the single fixed location. Environmental Protection Agency approval of a Quality Assurance Project Plan is required for valid data acquisition;
2. Add one suspended sediment monitoring site downstream of the tailrace. If equipment continues to be problematic, explore other options. Provide data representative of tailrace discharge conditions and river conditions for two years;
3. Provide data on the daily water level fluctuation changes from the past five years from stations listed in the PAD, and estimate fluctuations within Turners Pool assuming proposed operations and hydraulic conditions;
4. Identify the most appropriate techniques for bank stabilization given the existing and proposed hydraulic conditions;
5. Use previous bathymetric data, if available (Field 2007 recommends putting additional effort into finding a bathymetric survey from 1913 that was partially shown in Reid 1990), and current bathymetric information to look at areas of sediment accumulation. Determine areas of sediment deposition in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas. Habitat areas include but are not limited to coves (e.g. Barton Cove), back channels, islands, wetland habitats, shorelines, shoals, deep water areas, and channels;
6. Identify recreational uses and impacts in areas known to be impacted by accumulated sediment, such as Barton Cove;
7. Identify invasive species (plant or animal) present in the reaches and determine if erosion and sedimentation in any way contributes to the establishment and/or proliferation of these species;
8. Investigate the formation of beaches using remote sensing, LiDAR at low pool levels or some other mapping technique to understand the processes of beach deposition the distribution of beaches in the pool, the impact of beach deposition on habitat and species, and how can this be related to operation of NMPS;
9. Evaluate management strategies to address the release of accumulated sediment through Northfield Mountain Project works during upper reservoir drawdown or dewatering activities. FirstLight should specifically evaluate the feasibility of the installation of a physical barrier across the bottom of the intake channel designed to prevent the migration of sediment during future drawdowns of the upper reservoir;

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

10. Evaluate management strategies to minimize flow fluctuations within Turners Pool including coordination with upstream users;
11. Evaluate management strategies to minimize sediment released through spillway gates and the log sluice located near the bottom of the forebay adjacent to the Cabot Powerhouse during canal dewatering activities;
12. Identify a prioritized list of locations for bank stabilization projects in the Project Area;
13. Develop a map of land owned by FirstLight within 200 feet of the Connecticut River with an overlay of land use and vegetation cover. Provide land use options aimed at reducing bank erosion;
14. Any historic information of existing bed substrate material in the Turners Falls impoundment, bypass reach or downstream of the project should be collected and assembled. To the extent possible, the location of each sample should be made available on a map. The request for new data would stem from being able to make any valid comparison to changes in bed substrate at a given location, assuming the historic data exist;
15. Identify measures that could be taken to mitigate impacts to recreational use, habitat, or invasive species from sedimentation; and
16. Identify measures that could be taken to change or mitigate sediment starved reaches below the Turners Falls dam.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

Proponents' state: "*Many erosion studies have already been conducted and the cost of expanding the scope of some should be reasonable. A Full River Reconnaissance under the Erosion Control Plan for the Turners Falls Pool of the Connecticut River (Simons & Associates, Inc. dated June 15, 1999) is scheduled for 2013 and should accomplish many of the objectives listed above.*"

FirstLight's Rationale for Not Adopting the Proposed Studies

The majority of the tasks outlined in the Proponents' methodology are included in other studies found in the PSP, including:

- [Study No. 3.1.1](#) 2013 Full River Reconnaissance Study (Tasks 4, 12, 13);
- [Study No. 3.1.2](#) Northfield Mountain/Turners Falls Operations Impacts on Sediment Transport (Tasks 3, 4, 8);
- [Study No. 3.2.2](#) Hydraulic Study of Turners Falls Impoundment, Bypass Reach, and below Cabot Station (Tasks 3, 10, 16);
- [Study No. 3.3.13](#) Impacts of the Turners Falls Project and Northfield Mountain Project on Littoral Zone Fish Habitat and Spawning Habitat (Tasks 7, 15);
- [Study No. 3.3.14](#) Aquatic Habitat Mapping of Turners Falls Impoundment (Tasks 7, 15);

- [Study No. 3.4.1](#) *Baseline Study of Wildlife and Botanical Resources at Northfield Mountain Project Area, Turners Falls Impoundment, the Bypass Reach, and below Cabot Station* (Tasks 7, 15);
- [Study No. 3.5.1](#) *Baseline Inventory of Wetland, Wildlife, and Botanical Resources in the Turners Falls Impoundment, Bypass Reach, and Below Cabot Station and Assessment of Operational Impacts* (Tasks 7, 15); and
- [Study No. 3.6.6](#) *Assessment of Effects of Project Operations on Recreation and Land Use* (Task 6, 15)

Tasks 1, 2, and 9 of the Proponents' methodology are included in FirstLight's *Sediment Management Plan* (filed with FERC February 15, 2012). 2013 field activities are currently underway including continuous suspended sediment monitoring at the Route 10 Bridge, continuous suspended sediment monitoring of the intake and discharge lines at the Northfield Mountain Project, and suspended sediment data collection of the entire cross section of the river at the Route 10 Bridge over a range of flows during a one month period. At the end of the monitoring period (2015) FirstLight will propose measures to address the entrainment of sediment into the Project works during upper reservoir drawdown or dewatering activities.

FirstLight does not believe that it is necessary to install an additional suspended sediment monitoring device as requested in Task 2. Suspended sediment monitoring activities outlined in the *Sediment Management Plan* are more than adequate to provide the data requested above and have been approved by FERC, EPA and MADEP. Data collected at the Route 10 Bridge using the LISST-StreamSide, combined with the LISST-SL, will provide a detailed picture of suspended sediment in the mainstem Connecticut River. LISST-HYDRO devices located in the Northfield Mountain Plant are installed in-line to capture water withdrawn from the Northfield Mountain tailrace during pumping and transferred from the upper reservoir to the tailrace during generation. The combination of data collected at these locations will allow for a correlation to be made to determine what, if any, effects Northfield Mountain Project operations have on suspended sediment in the Connecticut River. In the *Sediment Management Plan* FirstLight proposes to continue sampling in 2013 and 2014, but may propose modifications to the sampling program based on sampling results.

FirstLight does not see the need to conduct historical comparisons of bathymetric data, or any geomorphic historical comparisons, for numerous reasons. First, as FirstLight has explained in many past FERC filings, rivers naturally migrate causing natural bank erosion, especially in the alluvial soils such as those flanking the Turners Falls Impoundment. Erosion could be caused by natural high flows, Project operations, boat wakes, upland management practices and other reasons. Therefore, sediment accumulation found throughout the Project area could be caused by several factors. Thus, it is unclear why understanding the historical changes in bathymetry, or other geomorphic processes, is required. Second, in its *Guide to Understanding and Applying the Integrated Licensing Process Study Criteria*, FERC reiterates that FERC uses current conditions as its baseline for evaluating project effects and alternatives and that this consists of the environment as it exists at the time of licensing.²⁸ FirstLight believes that the request is seeking a comparison to pre-raising-of-the-dam conditions. Finally, it is unclear how the requested data would inform potential PME measures. Additionally, FirstLight is not proposing to conduct topographic mapping or LiDAR along the 20-mile long Turners Falls Impoundment as existing topography is available from other sources and it is expensive. FirstLight will rely on the

²⁸ *Guide to Understanding and Applying the Integrated Licensing Process Study Criteria*, at p. 14 (Federal Energy Regulatory Commission, Office of Energy Projects, March, 2012)

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

existing upland mapping obtained from USGS National Map Viewer- more specifically, the USGS 10 meter digital elevation model (DEM).

FirstLight does not use the spillway gates or log sluice located near the bottom of the forebay adjacent to the Cabot Powerhouse during canal dewatering activities as suggested in Task 10, therefore management strategies to minimize sediment release will not be evaluated.

In regard to Task 16, it is FirstLight's belief that due to a combination of factors including the bed substrate of the Bypass channel, flood flows, and other hydrologic/hydraulic considerations discussed in [Study No. 3.2.2](#) that mitigation of sediment starved reaches below the Turners Falls Dam is not feasible. Stream power through the upper portion of the bypass reach where bedrock outcroppings are located during high flows is high enough to scour any sediment deposition that may occur.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.2 Water Resources*4.2.1 Watershed Wide Stormwater Model*

The CRJC requested a watershed-wide stormwater model of the entire Connecticut River Basin.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

CRJC lists the study's goals as (1) take a cumulative watershed approach to the management of surface water, a public trust resource; (2) determine the effect on public interests from projected future stormwater flows and the operation of the dams; and (3) recommend measures to manage stormwater flows through the operation of the dams to protect public interests. CRJC lists the study's objectives as (1) identify public interests in the watershed that have a nexus to dam operations; (2) develop an integrated, sharable, and scientifically-rigorous stormwater model for the entire watershed; (3) assess the cumulate effect of the dams on public interests, and (4) recommend license conditions to protect, preserve and enhance public interests.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

CRJC is not a resource agency.

Public Interest Considerations (18 CFR § 5.9(b)(3))

CRJC states that the public needs to know the effects the dams and their operations have on the natural and human environment, particularly in the future when CRJC believes precipitation is expected to be more extreme. CRJC also states that the public needs to know if and how the dams can be operated to benefit public interests in addition to hydropower. CRJC further states that the dams are the most significant factor in regulating stormwater flows in the Connecticut River.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

CRJC states that existing data on the location of resources of concern, while well intentioned, are too often incomplete or inaccurate. They state that since instream and riparian uses are closely tied to the frequency, depth and duration of the inundation by the river, stormwater information needs to be modeled and modernized, as precisely as possible, for accurate application.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

CRJC states that stormwater flows in the river effect nearly every resource under study, from providing whitewater recreational activities to sustaining floodplain biological communities. They state that the dams, in which they impound and then release the water, relies entirely on available stormwater.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

CRJC states that the proposed approach to analyzing water flows is the preferred methodology for forecasting, and evaluating environmental and economic outcomes based on various dam management scenarios. They state that this approach is being utilized in the Connecticut River Watershed Restoration Project that is being undertaken by TNC, USACE, UMass, and the USGS. CRJC states that this study is being performed to help determine how management of large mainstem and tributary dams and water

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

systems can be modified for environmental benefits while maintaining beneficial human uses such as water supply, flood control and hydropower generation.

CRJC notes that use of LiDAR is the preferred methodology for preparing digital elevation models. They noted the use of LiDAR at various locations; however, further detail on the method(s) to evaluate stormwater flows is not provided.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

CRJC states that development of the proposed stormwater model using LiDAR data could cost \$2,000,000 or more.

FirstLight's Rationale for Not Adopting the Proposed Studies

It is unclear from CRJC's study request if they are truly seeking a basin-wide stormwater runoff model as the proposed methodology does not provide enough detail. FirstLight believes that two other studies proposed herein will address the CRJC's study objectives and goals. Those studies, and how they would aid in addressing the CRJC's concerns, are listed below.

3.2.2 Hydraulic Model of Turners Falls Impoundment, Bypass Reach and below Cabot Station

FirstLight is proposing to develop two hydraulic models. A HEC-RAS hydraulic model of the Turners Falls Impoundment has already been developed. This model will predict the water surface profile of the Turners Falls Impoundment under a range of flows and starting downstream boundary conditions (in short, the water level at the Turners Falls Dam). This model was developed using bathymetric data collected in 2006. The second model will extend from Turners Falls Dam to the Holyoke Dam and will require use of the existing flood insurance study data for the communities along this reach of the river. The model will provide information on water surface elevations at different locations based for a range of flow conditions and project operations..

3.8.1 Evaluate the Impact of Current and Potential Future Modes of Operation on Flow, Water Elevation and Hydropower Generation

FirstLight is proposing to use an existing HEC-ResSim model of the Connecticut River basin that was originally developed by TNC, USACE, UMass and the USGS—the same model as cited by CRJC in their proposed methodology. This model will evaluate how current and alternative modes of operation can impact streamflow, water elevations and hydropower generation.

FERC's Study Request criteria require that the requester explain any nexus between project operations and effects on the resource to be studied, and how the study results would inform the development of license requirements 18 CFR § 5.9(b)(5). FERC's handbook "*A Guide To Understanding And Applying The Integrated Licensing Process Study Criteria*," issued March 2012, provides explanation on how FERC applies the study plan criteria in evaluating study requests. Per the guideline, relative to project nexus, it states the study request should clearly explain the connection between the project and its potential effect on the applicable resource. FirstLight does not see a nexus between the project and stormwater runoff, especially in the entire Connecticut River Basin. The only nexus between the project and the timing and magnitude of stormwater runoff the limited area of impervious surfaces associated with the project. CRJC's study request – a stormwater model of the entire Connecticut River Basin- has no nexus to the FirstLight hydropower facilities.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Also, per the guideline 18 CFR § 5.9(b)(6), under proposed methodology the requester is required to explain how any proposed study methodology is consistent with generally accepted practices in the scientific community. The guidance document further notes that the study methodology should be as detailed as possible. It was difficult for FirstLight to understand CRJC's proposed methods as it was detailed and intertwined operations modeling and stormwater modeling.

FirstLight believes that CRJC's request fails to meet FERC's nexus and methodology criteria. However, FirstLight believes that the combination of the hydraulic and operations models will address CRJC's concerns.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.2.2 Climate Change and Continued Project Operations

The Town of Gill, LCCLC, MADFW, CRWC, NHDES, and the USFWS requested studies on climate change as it relates to continued operation of the projects.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

The Proponents share the same study objectives: (1) quantify thermal loading contributed by each impoundment at each of the hydroelectric projects on the mainstem Connecticut River upstream through Wilder; (2) predict increases in temperature of the impoundments in the next 30-50 years due to climate change; (3) model the effect of various project modifications on river temperature under current conditions and climate change predictions; (4) use climate change prediction models to determine if the projects mitigate for generally warmer air and water temperatures by producing low greenhouse gas-emitting energy; and (5) determine how climate change will impact management of high flow events and whether changes to the dam structures would mitigate any adverse impacts of the existing project flood management protocols.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

USFWS states that the proposed study would help it accomplish its general goals of: (1) ensuring that PME measures are commensurate with project effects in order to meet regional fish and wildlife objectives; and (2) conserve, protect, and enhance fish and wildlife habitat affected by the projects. With specific reference to climate change, USFWS states that its goals are to minimize: (1) current and potential negative effects of project operations; (2) deep headpond drawdowns associated with the loss of stanchion logs, which it anticipates will increase due to more frequent climate change induced high flow events; and (3) project-related thermal increases to Connecticut River water temperatures. USFWS and others have developed a National Fish, Wildlife and Plants Climate Adaptation Strategy (Adaptation Strategy) which includes, among other actions, reducing non-climate stressors in order to help fish and wildlife adapt to climate change.

MADFW's statement of resource management goals is identical to USFWS's statement. MADFW further states that the study will facilitate collection of information needed to conduct effects analyses and develop PME measures. The Massachusetts Executive Office of Energy and Environmental Affairs has published the Massachusetts Climate Change Adaptation Report which identifies various strategies to preserve, protect, and restore natural habitats and the hydrology of watersheds.

NHDES states that it is responsible for issuing water quality certifications in New Hampshire under the Clean Water Act and for establishing and administering surface water quality standards. Surface water quality standards include designated uses, which include aquatic life, fish consumption, drinking water, recreation, and wildlife. NHDES also establishes criteria to protect the designated uses and meet the anti-degradation requirement. NHDES states that its surface water criteria for Biological and Aquatic Community Integrity provide for surface waters to maintain a balanced, integrated, and adaptive community of organisms with species composition, diversity and functional organization comparable to similar natural habitats, and that climate change effects on flow and temperature may impact aquatic life and other uses.

Public Interest Considerations (18 CFR § 5.9(b)(3))

CRWC states that the public has a strong interest in protecting and enhancing the fish, wildlife, and plants that depend on the Connecticut River and associated wetlands, banks, and floodplain habitats, and that the

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

study will enable the potential climate change induced effects on these resources and consider potential measures to minimize ecosystem degradation and enhance adaption to climate change.

LCCLC and Gill state that they support the USFWS's resource management goals.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

Proponents all include identical discussions of existing information. They state that the PADs for FirstLight's and TransCanada's projects contain no information relative to climate change and how climate change predictions may impact future operation of the projects, or how the projects either mitigate for or exacerbate predicted climate change impacts to freshwater ecosystems.

The proponents state that TransCanada's PAD includes data showing that water temperatures increase from the upstream end of the Wilder Project headpond to the Vernon Project tailrace, but do not link the data to climate change. They also state that TransCanada's project uses stanchion bays to relieve high water levels, but there is no information on how frequently the stanchions are removed or how climate change might affect the frequency and seasonality of removal, with potential impacts to resources in the project reservoirs.

The proponents provide data collected by the National Marine Fisheries Service that shows increasing air temperatures in the Northeast since 1900. They also provide analyses showing that mean water temperatures for the Vernon Dam impoundment increased between 1974 and 2010.

The proponents also reference the summary in the PAD of water quality data for the Turners Falls and Northfield Mountain Pumped Storage (NMPS) projects, and a 1991 study that showed a maximum temperature difference in the Turners Falls reach attributable to the NMPS project operation of 0.21 degrees Celsius.

Proponents' Explanation of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

The proponents state that the projects which dam the Connecticut River have created a series of long impoundments with slow water velocities that cause increased thermal loading and higher water surface temperatures than in free flowing sections of the river. They add that warmer surface waters may be discharged downstream and with a cumulative impact of elevated downstream temperatures. They add that climate change models of the Northeast forecast warmer air temperatures, more frequent high precipitation events, more heat waves, and increased incidence of short-term droughts. They indicate that effects include potential impacts to populations or loss of species not tolerant of warmer temperatures, citing potential impacts to American shad migration as an example. With regard to TransCanada's projects, the proponents state that deep drawdowns from removal of stanchions during high flow events could adversely affect reservoir resources, and that such drawdowns could occur more frequently in the future.

Proponents' Explanation of how Methodology is Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

The proponents state that the study would quantify the thermal loading contributed by each impoundment using data for bathymetry, storage capacity, hydrology, and project operations. The individual impoundment and cumulative surface water temperature predictions would be used to predict future warming based on climate change models.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

The study would then consider different potential measures to mitigate the effects of project and climate-change based warming, such as converting projects to run-of-river, making deep-water releases, removing dams, conducting large-scale riparian revegetation, and possibly others.

The proposed study would also “input to climate change models the amount of [greenhouse gas emissions] that would be generated if fossil fuel plants were producing the equivalent amount of net energy as the five hydropower projects to determine the impact on air and surface water temperatures.”

Climate change models would be used to predict whether the frequency and timing of high flow events is likely to change in the future. If the models predict that the frequency or timing of high-flow events necessitating the removal of stanchion bays will increase, then the proponents would have the Commission require the licensee to evaluate structural or operational alternatives to mitigate adverse impacts of existing flood management protocols.

Proponents’ Description of Level of Effort and Cost, and Why Alternative Studies are Insufficient to Meet the Stated Information Needs (18 CFR § 5.9(b)(7))

USFWS does not include any information regarding level of effort and cost, or why alternative studies are insufficient to meet its stated information needs.

NHDES states that the cost of a thermal loading analysis would be low to moderate because bathymetry data for the Turners Falls Impoundment and Northfield Mountain upper reservoir already exist, and that the remaining work consists of loading data into an appropriate model and computing the estimated load, then comparing it to surface water data from climate change prediction models. It also states that the high flood protocol study should have a low to moderate cost because climate change models already exist. The comments of MDFW, CRWC, LCCLC and Town of Gill are identical to NHDES’ comments.

FirstLight’s Rationale for Not Adopting the Proposed Study

Although it is reasonable to conclude that the Connecticut River project impoundments affect water temperatures, and that regional air and water temperatures may be elevated in the future because of climate change, the proponents have failed to explain how their proposed study is consistent with accepted practice. While it is possible to estimate future water temperature conditions in the project impoundments with conventional hydrologic studies, monitoring techniques, and predictive models, the proponents have made no effort to explain how such water temperature data and predictions would be married with climate change models to accurately predict the combined effects of the projects and climate change on Connecticut River water temperatures over time. Indeed, they have not identified any climate change models that are sufficiently sensitive to accurately predict changes in the temperatures of individual rivers or the frequency or seasonal distribution of high flow events in the short-term, let alone for the 30-50 year period of a new license. In fact, they identify no specific models at all. The literature citations to the USFWS comments merely cite generally a 2009 report on global climate change impacts in the United States which includes a three page summary of potential impacts to the Northeast and the (now final) Adaptation Strategy. The proponents have also made no effort to show why conventional hydrologic studies, monitoring requirements, and reopener provisions that have been employed in hundreds of other hydroelectric license proceedings are not adequate to address potential impacts of climate change that, to the extent they occur, are likely to develop in an incremental manner over many years. In sum, the study proponents have asserted, but in no way shown, that their requested study is consistent with accepted practice.

The proponents’ failure to articulate a detailed, credible study proposal for linking regional climate change to water temperature effects from the Connecticut River hydroelectric projects, individually or

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

cumulatively, is not surprising. A July 2012 report by the Columbia Law School Center for Climate Change Law, *Consideration of Climate Change in Federal EISs, 1009-2011*, reviewed a database of 227 federal agency EISs that substantively address climate change related impacts. The report finds:

While greenhouse gas emissions from projects are frequently addressed in EISs, the effects of climate change on the proposed projects are considered far less often. *Preparing agencies face considerable scientific uncertainty about the severity and exact nature of climate change impacts at the regional level, and projections are even more difficult at the local level.* EISs of briefly analyze the impacts of climate change on the region or locality in which the project is located without addressing the direct impacts of climate change on the project itself. (p. 8) (emphasis added)

With specific regard to USFWS EISs, the study found:

USFWS EISs address the impacts of climate change on a project primarily as they relate to specific plant and animal species. EISs address the effects of climate change on the habitat, food resources and behavior of individual species, especially those federally listed as endangered or threatened. *Analysis of the impact of climate change on a project is often limited to a brief discussion of climate impacts on wildlife species or vegetation as a secondary or compounding impact.* These species are discussed primarily in terms of their vulnerability to non-climate related impacts from the project (such as habitat loss or noise), and climate change is mentioned as an additional factor that might increase the cumulative impact on the species. (footnote omitted) (p. 11) (emphasis added)

The Commission has recognized the inadequacy of current day computer modeling to develop information useful for development of specific license requirements in several recent cases. *See, e.g.,* Study Plan Determinations for the Susitna-Watana Project No. 14241 (Feb. 1, 2013) at B-8 (rejecting agency requests for comprehensive study of climate change impacts on all resources in the river basin potentially affected by the proposed projects because the results would be too uncertain to rely upon for development of license conditions, the study would be very costly, and existing hydrologic studies and monitoring techniques are sufficient to develop license conditions); Lake Powell Pipeline Project No. 12966 (Jan. 21, 2009) Appendix A at 1 at 14-16) (for proposed water supply project with hydroelectric component, accepting applicant's proposal to use literature review and existing US Bureau of Reclamation regional climate change model to estimate potential effects of climate change on Colorado River flows, but finding an absence of climate change models sufficiently finely tuned to make reservoir operation decisions); and Toledo Bend Project No. 2305 (August 6, 2009) Appendix A at 16-17 (finding no evidence of climate change assessment with the accuracy to predict specific resource impacts that could serve as the basis for developing license conditions; and determining that conventional hydrologic studies and monitoring techniques are adequate for the purpose).

In sum, the proponents have not provided any reason for the Commission to require FirstLight to develop a highly problematic study that it is unlikely to produce any information that would be useful for the development of license conditions, particularly when existing methods and approaches are sufficient to develop information that will enable the Commission, licensee, and resource agencies to develop timely, appropriate responses to climate change impacts.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.3 Fish and Aquatic Resources*4.3.1 Shad Population Model for the Connecticut River***Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))**

In their study request letters, USFWS, NHFG, MDFW, NHDES, CRWC, and TU request that FirstLight develop an American shad population model utilizing existing data to quantify how project operations and potential restoration/mitigation measures impact the Connecticut River shad population.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

Requesting agencies and TU identified Resource Management Goals for this study as defined by the *Management Plan for American Shad in the Connecticut River Basin* (1992). Specific management objectives in the plan include the following: achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually; achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem; and maximize outmigrant survival for juvenile and spent adult shad.

In addition, requests identify a number of broader resource PME goals under the overall relicensing process.

Public Interest Considerations (18 CFR § 5.9(b)(3))

USFWS is a federal resource agency. NHFG, MDFW and NHDES are state resource agencies. CRWC and TU are not public agencies.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

As described in the PAD, the annual number of adult shad passing into the impoundment below Turners Falls rose, with substantial year-to-year variation, until 1992 when numbers began to decline. This decline was not predicted by the predictive abundance model developed by Connecticut Department of Energy and Environmental Protection (CTDEEP). The decline has been noted in other Atlantic coast shad populations as well. Several factors may contribute to the recent decline in the Connecticut River American shad population. Factors include: 1) increased predation mortality, especially by striped bass (Savoy & Crecco, 2004); 2) competition by gizzard shad (Gephard & McMenemy, 2004); and/or 3) reduction of repeat spawners (Leggett et al., 2004). In 2012 the largest number of American shad were lifted at Holyoke Dam since 1992. While reports indicate that the American shad run on the St. John's River in 2012 was also higher than recent years, not all Atlantic coast river experienced similar increases.

Appendix G of the PAD identifies over 30 upstream and downstream fish passage studies that have been conducted at the Turners Falls Project going as far back as 1969 to as recently as 2010. FirstLight has worked diligently with agencies to evaluate effectiveness of fish passage facilities at the Turners Falls Project, including identification of potential improvements that FirstLight anticipates will be evaluated under the relicensing process, such as designs developed for a fish lift to replace the existing Cabot Fishway that were developed in consultation with representatives of CRASC.

Starting in 2008, biologists from the CAFRC have evaluated shad passage through the new Gatehouse Fishway entrance that was constructed in 2007. Results of these evaluations and review of shad counts conducted by FirstLight have demonstrated that shad successfully pass through the new entrance flume, and have also led to iterative modifications since operation of the new entrance was initiated. These

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

improvements have included the installation of flow controls within the fishway entrance gallery, modification of canal operating protocols, relocation of water level sensors, and installation of a temporary rock ramp from the bottom of the canal to the original entrance (the ramp is no longer in place).

Currently, shad appear to pass readily through the new entrance, but not through the original entrance. Flow control changes intended to ensure adequate flow through the new entrance and to the Spillway Fishway have resulted in excessive velocity and turbulence at the original entrance that may be inhibiting shad passage. FirstLight continues to work with CAFRC and agencies to assess alternative to improve passage at the original entrance.

Historic upstream passage telemetry studies have shown that the Northfield tailrace had no clear effect on shad movement through the impoundment. Some shad turned back upon reaching the Northfield tailrace both during operational and non-operational periods. More recently, the USFWS Connecticut River Coordinator and CAFRC have released radiotagged shad at various points in the river and tracked their movements from the release point to Vernon Dam. Results from that study will be available once data analysis has been completed.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

Existing project operations and fish ladder efficiencies have a direct effect on shad populations in the Connecticut River. Low upstream passage efficiencies and delays restrict river access to returning shad and can affect the ability of American shad to reach upstream spawning grounds while the ability to effectively pass downstream may affect outmigration and potential for repeat spawning.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

Population models are commonly used to assess anthropomorphic and natural impacts and are consistent with accepted practice. A model similar to this request was constructed for the Susquehanna River by Exelon (FERC #405, RSP 3.4). The model is constructed in Microsoft Access, and should be adaptable to allow the input of new data and other inputs. Proponents' listed a variety of model inputs.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

The Proponents' state: *"Neither First Light nor TransCanada have proposed any study to meet this need. Estimated cost for the study is expected to be low to moderate. As the model describes the impacts of multiple projects and two owners, both project owners would share the cost of model development."*

FirstLight's Rationale for Not Adopting the Proposed Studies

FirstLight is proposing a suite of upstream and downstream fish passage studies, an instream flow study in the Turners Falls bypass reach and downstream of the Turners Falls and Northfield Mountain Projects, and a desktop entrainment analysis for the Projects. Results of these studies, coupled with the vast number of previous American shad passage studies at the project facilities should be more than sufficient to assess fish passage needs and potential modifications to existing facilities necessary to achieve improved fish passage efficiency. Further, a predictive abundance model already exists which, while historically generating relatively accurate results, did not predict the downturn in returning shad numbers that likely result from difficult to predict variables such as competition and predation of other species. The study requests also include the ability for the model to analyze sensitivity of fish passage efficiencies at all Connecticut River Projects. While there may be a cumulative effect on the overall American shad

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

population in the river, efficiency at a given upstream or downstream hydroelectric facility is independent of FirstLight's fish passage facility efficiencies.

It is unclear to FirstLight how output from the requested population model will contribute to FERC's analysis of project effects and potential PME measures as compared to results of existing and proposed fish passage effectiveness testing.

4.4 Aesthetic Study*4.4.1 Noise Level Determination for Northfield Mountain Project Operations***Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))**

The Proponent states that the goal of the study is to evaluate the current level of noise produced by the Northfield Mountain Project as heard by neighbors to the project, to determine if the proposed changes to the project increase the noise level, and to mitigate any present and future noise.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

This request was made by a private citizen, not a resource agency.

Public Interest Considerations (18 CFR § 5.9(b)(3))

The Proponent states that it is in the public's interest that this project and its expansion not negatively impact the quality of life for Northfield Mountain Project's neighbors. Noise negatively impacts quality of life.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

The Proponent does not identify any existing information pertaining to noise levels at the Northfield Mountain Project.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

The Proponent states that: *"Northfield Pump Storage Project runs pumps to move water to a holding reservoir, and turbines to harvest energy from the water. Both these operations involve large equipment that makes a lot of noise. This noise may be broadband, low frequency, or infrasonic pressure or vibration. Increasing the pump and/or turbine operation in frequency, size, or number could impact the amount of noise this equipment makes, so that it is more audible to neighbors. Noise might need to be mitigated e.g. via insulation, or prescribed combinations of equipment running, etc. to reduce noise impact on neighbors."*

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

Additionally the Proponent proposes a 2-part process:

- Part A (1 year): neighbors to the project record unexplained noises including what type of noise and when, compare these lists with operating records of the Northfield Mountain Project to see if correlation exists
- Part B (1 year): If correlation exists, further study would be needed using MADEP protocols. This could be done simultaneously with Part A to increase turn-around time, or left until afterwards on the change it would not be needed. It could also be the first step in the process if Part A was not considered necessary.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

The Proponent states that the cost of determining a baseline noise level and comparing any old/new noises with operating records is relatively low. The Proponent also states, if it is determined that the Northfield Mountain Project is making noise then the cost of measuring the noise level would possibly be in the tens of thousands of dollars. Finally, the Proponent states that mitigating the noise would likely cost several hundred thousand dollars.

FirstLight's Rationale for Not Adopting the Proposed Studies

Due to the location of plant infrastructure deep inside of a mountain, FirstLight does not believe noise levels related to Project operations are at a level outside of the plant that could negatively impact the quality of life of Project neighbors. FirstLight believes the mountain, which the plant is located inside of, acts as a natural insulator of noise. This belief has been confirmed by FirstLight personnel who work outside of the mountain and have not heard excessive noise levels during Project operations. In addition, due to the unique configuration of the plant inside of a mountain, even in the event noise levels were found to be at a level effecting Project neighbors, PME measures would a) not be possible, or b) be far too expensive to be feasible.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.5 Recreation and Land Use**4.5.1 Contingent Valuation Study**

New England Flow, American Whitewater, and The Appalachian Mountain Club (collectively referred to as FLOW) have requested that FirstLight conduct a contingent valuation study of providing paddling flows (e.g., for kayaking, canoeing, whitewater rafting, instructional paddling, and paddle-boarding) in the Turners Falls Project bypass reach.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

FLOW states that the goal of the requested study is to examine the regional economic benefits of various flow release alternatives in the Turners Falls Project bypass reach.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

FLOW is not a resource agency.

Public Interest Considerations (18 CFR § 5.9(b)(3))

FLOW states that the public interest is economic stimulus.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

FLOW states that it is unaware of any existing information regarding the economic potential of the Turners Falls Project bypass reach for paddling flows. It does, however, cite to a study of the economic impacts of whitewater boating on a river in Vermont.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

FLOW states that understanding the economic values that could be provided by flow releases in the Turners Falls bypass for paddling recreation will assist FERC and other stakeholders in balancing the trade-offs associated with lost generation.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

FLOW states that the only methodology that will assess the economic value of paddling flows in the Turners Falls bypass reach is through a contingent valuation study that measures an individual's willingness to pay. FLOW also states that contingent valuation studies provide reliable, comparable information that can be used to frame license requirements.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

FLOW states that data should be collected through surveys and interviews of known paddling clubs, customers of commercial whitewater outfitters, outfitters of tubing equipment and kayakers, canoeists, and rafters of varying abilities. FLOW fails to describe the level of effort or cost that such data collection would entail or the level of effort and cost that other elements of a contingent valuation study would entail.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight's Rationale for Not Adopting the Proposed Studies

FirstLight disagrees that there is a nexus to Project operation and effects. Contingent valuation studies do not produce a reliable assessment of the potential economic impact of adding recreational opportunity to an area. Further, FERC has consistently found that monetization of non-power resources is inadequate in the context of assessing non-power values under Sections 4(e) and 10(a)(1). The Commission has stated that “for non-power resources such as aquatic habitat, fish and wildlife, recreation, and cultural and aesthetic values, to name a few, the public interest cannot be evaluated adequately only by dollars and cents.”²⁹ In a recent Study Plan Determination, FERC did not adopt a request for a proposed economic study of non-power resources. FERC stated that “[n]othing in the [Federal Power Act] requires the Commission to place a dollar value on non-power resources. Nor does the fact that because the Commission assigns dollar figures to the licensee’s economic costs require that the Commission do the same for non-power resources.”³⁰

FirstLight is proposing to conduct several studies related to recreational use and demand at the Turners Falls Project, including a controlled whitewater flow evaluation in the Turners Falls Project bypass reach, an assessment of access needs for paddling in the Project vicinity, and assessments of use and demand. These studies along with studies regarding other assessments of power and non-power resources at the Turners Falls Project bypass reach will provide FERC with the information it needs to craft a new license for the Project that gives equal consideration to power and non-power values and is in the public interest.

FirstLight also disagrees with FLOW’s assertion that the only methodology that will assess the economic value of paddling flows in the bypass reach is through a contingent valuation study. Contingent valuation studies are not generally accepted within the scientific community. It is well settled that contingent value surveys are expensive, subject to bias,³¹ and even “[s]tudies conducted in controlled experimental settings suggest that . . . contingent valuation . . . methods may overestimate values³² producing “implausible” results³³ that fail by trying to reduce FERC’s public interest test to a mere mathematical exercise.”

Finally, FERC’s Study Request criteria require that the requester describe considerations of level of effort and cost. 18 CFR § 5.9(b)(7). FERC’s handbook “*A Guide To Understanding And Applying The Integrated Licensing Process Study Criteria*,” issued March 2012, provides explanation on how FERC applies the study plan criteria in evaluating study requests. With respect to the level of effort and cost

²⁹ See e.g., *Great Northern Paper, Inc.*, 85 FERC ¶ 61,316 (1998), *reconsideration denied*, 86 FERC ¶ 61,184 (1999), *aff’d*, *Conservation Law Foundation v. FERC*, 216 F.3d 41 (D.C. Cir. 2000) (nothing in the FPA requires the Commission to place a dollar value on nonpower benefits; nor does the fact that the Commission assigned dollar figures to the licensee’s economic costs require it to do the same for nonpower benefits.); *City of Tacoma*, 84 FERC ¶ 61,107 (1998), *order on reh’g*, 86 FERC ¶ 61,311 (1999), *City of Tacoma v. FERC*, 460 F.3d 53 (D.C. Cir. 2006).. See also, *Namekegon Hydro Co.*, 12 FPC 203, 206 (1953), *aff’d*, *Namekegon Hydro Co. v. FPC*, 216 F.2d 509 (7th Cir. 1954) (when unique recreational or other environmental values are present such as here, the public interest cannot be evaluated adequately only by dollars and cents); and *Eugene Water & Electric Board*, 81 FERC ¶ 61,270 (1997), *aff’d*, *American Rivers v. *Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

criteria, FERC explains that to estimate the level of effort and cost, a study proponent should, at a minimum, estimate the number of hours or person-days that would be required to conduct the requested study and identifiable tasks (e.g., report preparation). FERC states that the information gained under this criterion is also useful in weighing the costs and benefits of different methods for obtaining the needed information. While FERC may not reject a study based on cost alone, information on cost and level of effort is necessary for FERC to determine whether the requested information is in line with the magnitude of the potential effect of the Project on particular resources.

The proposed study does not meet this criterion. While FLOW states that data should be collected through surveys and interviews of known paddling clubs, customers of commercial whitewater outfitters, outfitters of tubing equipment and kayakers, canoeists, and rafters of varying abilities they fail to describe the level of effort or cost that such data collection would entail or the level of effort and cost that other elements of a contingent valuation study would entail.

In sum, FirstLight has not included FLOW's proposed study in its PSP because the proposed contingent valuation study will not inform the development of license requirements, is not accepted within the scientific community, and does not describe considerations of level of effort and cost.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.5.2 *Mitigation Impacts of the Connecticut River and Loss of Whitewater Recreation at and above Turners Falls Dam*

New England Flow, American Whitewater, and The Appalachian Mountain Club (collectively referred to as FLOW) have requested that FirstLight conduct a study to assess regional whitewater boating resources in order to determine off-site mitigation.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

FLOW states that the goal of the study is to assess the presence, quality, access needs, flow information needs, and preferred flow regimes for regional whitewater boating resources that would mitigate for the loss of whitewater recreation at the Turners Falls Dam.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

FLOW is not a resource agency.

Public Interest Considerations (18 CFR § 5.9(b)(3))

FLOW states that the Turners Falls dam removes the public's opportunity to enjoy a whitewater boating resource and that conducting studies and implementing necessary measures to ensure the public has access to whitewater recreational resources is in the public interest.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

FLOW states that current and historic project operations at the Turners Falls Dam do not provide meaningful information for determining off-site mitigation.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

FLOW states that the construction of the Turners Falls Dam dewatered the Turners Falls bypass reach and the creation of the Turners Falls Impoundment "drowned upstream rapids, which would be sufficient cause for off-site mitigation."

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

FLOW proposes the following "process" steps: desktop analyses of candidate rivers, resource agency identification and feasibility assessment, and inter-agency meetings with stakeholders to explore opportunities for mitigation.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

FLOW states that it is willing to work with FirstLight on an off-site mitigation study to keep costs reasonable and the quality of information high. FLOW has also proposed that FirstLight conduct a controlled-flow whitewater boating study.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight's Rationale for Not Adopting the Proposed Studies

FLOW's study proposal is in essence a request to explore off-site mitigation opportunities to compensate for alleged impacts caused by initial Project construction. FERC's analysis, however in a relicensing proceeding is based on existing conditions.³⁴ FERC's environmental review focuses on the fact that the Project already exists and is part of the existing environment.³⁵ In its *Guide to Understanding and Applying the Integrated Licensing Process Study Criteria*, FERC reiterates that FERC uses current conditions as its baseline for evaluating project effects and alternatives and that this consists of the environment as it exists at the time of licensing.³⁶ The results of the proposed mitigation study would not inform the development of license requirements to address effects, if any, of Turners Falls Project operation on whitewater boating.

FirstLight agrees that a controlled-flow whitewater boating and paddling study may have a nexus to the current operation of the Turners Falls Project and has included this study proposal in the PSP (Study 3.6.3). FirstLight's proposed study will evaluate the effects of Turners Falls operation on the availability of whitewater and other recreational boating in the Turners Falls bypass reach. FirstLight, however, has not included the proposed mitigation study in the PSP because it is not a study designed to evaluate the effects of current Project operation on recreational boating.

Similarly, FLOW's proposed study does not describe a study methodology, but instead a process for identifying off-site mitigation measures. Finally, FLOW fails to explain why its proposed whitewater boating study will not suffice at evaluating the effects, if any, of Turners Falls Project operation on the availability of whitewater boating in the Turners Falls bypass reach.

In sum, FirstLight has not included the proposed request to assess regional whitewater boating resources in order to determine off-site mitigation in the PSP because (1) it is not a study request but a proposal to investigate potential PMEs, (2) it is based on an assumption of pre-project conditions and thus there is no nexus to Project operation, and (3) fails to describe methodology, and level of effort and cost.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.6 Cultural Resources*4.6.1 Assess Preservation of Cultural, Historical and Educational Resources*

Appalachian Mountain Club, Vermont River Conservancy, and Friends of the Connecticut River Paddlers' Trail (collectively referred to as "AMC") have requested a study regarding public education of the area's cultural resources and preservation of historical documents.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

AMC states that the goal of the study is to determine what actions should be taken to educate the public about an historical site that lies under the Turners Falls Impoundment, to determine what actions should (or should not) be taken to preserve artifacts, and to identify, preserve, and make available historical engineering drawings for the Projects to historians and researchers.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

AMC is not a resource agency.

Public Interest Considerations (18 CFR § 5.9(b)(3))

AMC states that historical records and education are valuable public resources.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

AMC states that there are many history books addressing the 1676 battle at Turners Falls and the King Phillip's War. AMC also cites two books regarding the engineering history of the Turners Falls site.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

AMC states that the Turners Falls Impoundment covers the site of the 1676 battle and probably artifacts. AMC also states that there may be Indian artifacts or burial grounds on the Turners Falls Project lands. AMC states that presumably FirstLight has in its possession historical records relating to the construction of the Turners Falls dam.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

AMC does not recommend a methodology other than to suggest that study methodology with respect to Native American use of the areas should be left to the Tribes, and to regional professional historians and others. AMC also notes the identity of a local organization with expertise in historical preservation and museum preservation.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

AMC does not describe level of effort and cost other than to state that there are academics and museum personnel who could do this study and make recommendations.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight's Rationale for Not Adopting the Proposed Studies

To the extent that AMC's request is to study or provide mitigation, protection, and enhancement for impacts resulting from original construction of the Turners Falls dam, as discussed previously in [Section 4.5.2](#) of the PSP, such an approach would be inconsistent with FERC's environmental baseline, which looks at the impact of current Project operation and thus would not inform the development of conditions for a new license for the Turners Falls Project.

AMC's request is not a request for a study, but a request for PME. FirstLight is proposing to conduct a Phase 1A archaeological survey and a reconnaissance level historic structures survey for both the Turners Falls and Northfield Mountain Projects. See Studies 3.7.1 and 3.7.2. The results of those surveys will inform the need for more intensive cultural resources surveys. At the conclusion of cultural resources surveys, depending on survey results, FirstLight may prepare draft and final HPMPs, which will propose protection and mitigation measures for adverse effects, if any, to historic properties that are caused by the continued operation of the Project. It is premature to determine which measures, including education and preservation measures, should be included in the draft or final HPMP.

In sum, FirstLight has not included the proposed request for an assessment of cultural, historical and educational resources in the PSP because (1) it is not a study request but a proposal for PMEs, (2) to the extent it requests an assessment of pre-project conditions, there is no nexus to Project operation, and (3) fails to describe methodology, and level of effort and cost.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

4.7 Other Project Relative Issues**4.7.1 *Feasibility of Converting the Northfield Mountain Pumped Storage Project to a Closed-Loop or Partially Closed Loop System***

The Town of Gill, LCCLC, FRCOG, FCD, and CRWC requested studies on the feasibility of converting the Northfield Mountain Pumped Storage Project into a closed-loop or partially closed-loop system.

Proponents' Description of Study Goals and Objectives (18 CFR § 5.9(b)(1))

Proponents state that the objectives of the study would be to determine: (1) candidate locations for placement of a lower reservoir; (2) costs and logistics of construction and modification of the current facility to convert to a closed-loop or partially closed-loop system; (3) projected savings associated with eliminating need for ongoing mitigation measures, both for stabilizing river banks as well as likely modification to operations that the facility will be required to implement in order to protect habitat and native fauna; and (4) other ancillary costs or savings, such as eliminating requested studies, operational changes, or mitigation measures.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

The Town of Gill, LCCLC, FRCOG, FCD, and CRWC are not resource agencies.

Public Interest Considerations (18 CFR § 5.9(b)(3))

Proponents state that it is in the public interest to ensure high quality habitat for migratory diadromous fish, and the Northfield Mountain project reduces the quality of habitat for these species through increased turbidity and deposition of fine-grained sediments and that the likelihood of entrainment and entrainment mortality.

Proponents' Description of Existing Information (18 CFR § 5.9(b)(4))

Proponents state that data on the environmental effects of the Northfield Mountain project and other facilities that use fresh or salt water for generation and/or cooling are widely available, citing data submitted in the PAD and the required conversion of a coal powered plant from open to closed cycle operation.

Proponents' Description of Nexus to Project Operation and Effects (18 CFR § 5.9(b)(5))

Proponents state that converting the Northfield Mountain project to a closed loop facility would eliminate environmental effects on fisheries, water quality, and erosion of farmland.

Proponents' Explanation of How Methodology Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

Proponents' methodology includes: (1) collate existing geological and hydrologic information of areas surrounding Northfield Mountain, including preliminary design plans for suitable facilities able to accommodate the existing and proposed discharges; (2) provide an engineering analysis of structural modifications necessary to accommodate a full or partial lower reservoir in an alternate nearby location; (3) provide information on whether and how a smaller lower reservoir would act as a buffer to river level fluctuations and change the hydrologic pattern of flow on the Connecticut River, the water quality effects, and decrease the possibility of entrainment; (4) provide an analysis on water losses from evaporation and

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

leakage and how much make-up water would be needed during normal operations by season or month; (5) identify and make available any similar studies conducted during the planning phase of the existing facility in the 1960s or any other time; (6) provide a cost estimate of each option considered and evaluated; and (7) provide an itemized cost estimate of how halting use of the Connecticut River as a lower reservoir would affect other costs, such as eliminating the erosion control program, any ancillary changes to generation at the projects, and fish protection measures.

Proponents state that the study methods are consistent with accepted practice for weighing costs and benefits of environmental impacts.

Proponents' Statement Regarding Level of Effort, Cost, and Why Alternative Studies Will Not Suffice (18 CFR § 5.9(b)(7))

Proponents' state: "The level of effort to compile existing information and to make the data available in a map should be low, as should development of contingency scenarios. Development of contingency scenarios would be low. The majority of the effort of this study request is essentially office work with some engineering and design work required to scope likely costs of various scenarios."

FirstLight's Rationale for Not Adopting the Proposed Studies

The proponents' suggestion that a useful study could be accomplished at low cost with "some engineering and design work" demonstrates a profound lack of understanding of the study costs involved in any major new or modified ground disturbing project. Any study of converting the Northfield Mountain facility to a closed-loop system with a new lower reservoir would essentially require a comprehensive analysis comparable to that required for development of a license application for a major new project or major license amendment. It would necessarily include a comprehensive review of existing geological and hydrologic information and new site-specific geologic investigations of any places where the new lower reservoir and associated project facilities (e.g., new forebay, tunnels, penstocks, and powerhouse), detailed engineering feasibility and costs analyses of potential lower reservoir alternative sites, project facilities, and reconfiguration of the upper reservoir to operate in connection with the new reservoir and facilities, and studies and analyses of environmental effects in any area where a new lower reservoir would be located. The site investigations from the 1960s would be next to, if not entirely, useless for these purposes.

Moreover, the Commission has recently stated that while the Federal Power Act authorizes it to require modifications to an applicant's proposal to ensure that the project is best adapted to a comprehensive plan for developing or improving a waterway, the Commission does not believe it has authority to require a license applicant to construct and operate an entirely different project from the one it has proposed. *See Erie Boulevard Hydropower, L.P.*, 120 FERC ¶ 61,267 at P 97 (2007). That would certainly be the case here.

4.7.2 Creation of a Decommissioning Fund

The NPS and, jointly, the AMC, Vermont Resources Conservancy (VRC), and Friends of the Connecticut River Paddlers Trails (FCRPT) (collectively, the study proponents) have requested studies related to decommissioning of the licensed projects. NPS seeks a study of the "financial production" of each project, which would be used in the Commission's public interest analysis to evaluate a requirement for the licensee to have a decommissioning fund for each project. AMC, VRC, and FCRPT seek a study to "determine the appropriate decommissioning costs at the end of the project's lifetime and how such costs should be funded . . . in advance."

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

Proponents' Descriptions of Study Goals and Objectives (18 CFR § 5.9(b)(1))

The study proponents state that the goal of their proposed studies is the establishment of a decommissioning fund, so that the public will not be burdened by the cost of decommissioning the projects.

Relevant Resource Management Goals (18 CFR § 5.9(b)(2))

NPS is a federal resource agency. NPS states generally that its management goals with respect to the Connecticut River watershed are to promote a “water-based approach to conservation, outdoor recreation, education, and sustainable economic opportunities” and to “establish community-driven conservation and recreation for the 21st century.”

Public Interest Considerations (18 CFR § 5.9(b)(3))

AMC, VRC, and FCRPT are not resource agencies. They state that the requested study is in the public interest because the project might one day be abandoned and the public might be required to bear the costs of remediating the site(s).

Proponents' Description of Existing Information and Need for Additional Information (18 CFR § 5.9(b)(4))

The study proponents allege that there are thousands of abandoned dams on New England waterways. They add that the physical and financial viability of the projects is at risk from various factors, such as extraordinary storms, foreign ownership, and international currency market fluctuations. NPS contends that decommissioning funds are commonly required for federally licensed facilities.

AMC, VRC, and FCRPT state that there appears to be no published information on the economic viability of the projects, which they believe is needed in order to establish their proposed decommissioning funds. NPS says essentially the same thing.

Proponents Description of Nexus Between Project Operation and Effects on Resources (18 CFR § 5.9(b)(5))

The study proponents state that there is a direct nexus between Project operations and the economic viability of the projects.

Proponents Explanation of How Methodology is Consistent with Accepted Practice (18 CFR § 5.9(b)(6))

The study proponents state that the financial viability portion of the study would follow “normal procedures” in accounting and financial management.

Proponents' Description of Level of Effort and cost, and Why Alternative Studies are Insufficient to Meet the Stated Information Needs (18 CFR § 5.9(b)(7)).

The proponents state that the study would be “relatively inexpensive” and that they are not aware of any means other than decommissioning funds to protect the public.

*Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)*PROPOSED STUDY PLAN

FirstLight's Rationale for Not Adopting the Proposed Studies

The proposed studies are not appropriate because the Commission has consistently denied requests for the establishment of decommissioning funds in new licenses. The Commission has found that such funds “unnecessarily tie[] up substantial amounts of the capital of financially sound licensees . . . for extensive periods.” Project Decommissioning at Relicensing; Policy Statement, FERC Stats. and Regs. ¶ 31,011 at p. 31,234 (1995). Also, the Commission has not required a decommissioning fund where: (1) there is no evidence the project is economically or physically unsound; (2) no party has suggested decommissioning in the foreseeable future; (3) there is no evidence indicating that the physical life of the project will end during the term of the new license; or (4) there is no indication that the licensee would lack the financial resources to decommission the project if it were to be decommissioned. *See, e.g., Wis. Valley Improvement Co.*, 80 FERC ¶ 61,054 at p. 61,164 (1997); *N. States Power Co.-Wisconsin*, 78 FERC ¶ 61,120 at p. 61,460 (1997); *N. States Power Co.*, 78 FERC ¶ 61,363 at p. 62,511 (1997); *Wolverine Power Supply Coop., Inc.*, 85 FERC ¶ 61,030 at p. 61,090-91 (1998); *Potlatch Corp.*, 72 FERC ¶ 61,029 at p. 61,173 (1995). All these factors are present here. The Commission’s policy has been found to be reasonable on judicial review. *See Kelley v. FERC*, 96 F.3d 1482, 1490 (D.C. Cir. 1996). Since there is no reason to impose the requested license condition, there is no reason to require the proposed studies.

In addition, the study requests are flawed because:

- The proponents’ suggestion that extreme weather events put the licensed projects at risk has no support. The proponents have made no effort to explain how the existence of abandoned dam in New England, the vast majority of which are on small rivers or streams, and which were built as often as two hundred years ago using long since outdated construction methods, bear any relation to Commission-licensed projects, which are subject to perhaps the most rigorous dam safety requirements in the world.
- The useful physical and economic life of the projects cannot be determined. The Turners Falls project has been operating continuously for decades and there is no indication it cannot continue to be operated indefinitely. Similarly, all of the 17 pumped storage projects licensed by the Commission since 1958 and constructed are still operating and there is no reason to think any of them is approaching the end of its physical or economic life. Northfield Mountain is no different.
- The proponents’ unsupported assertions notwithstanding, there are no “normal procedures” for estimating the potential cost of hypothetical decommissioning at an uncertain future time which could be far beyond the life of the next licenses, or even the next licenses after those. Any number of decommissioning scenarios that might be considered, and it is impossible to know with any certainty in advance which scenario would be adopted, let alone what engineering or environmental reviews would be appropriate, or the distant future legal and regulatory landscape.

Finally, NPS has made no effort to explain how the proposed study relates to its generally stated goals of promoting conservation and recreation. Rather, it merely cites the hypothetical future default which the Commission, with judicial approval, has stated is insufficient to require a decommissioning fund.

RE: Connecticut River concerns -

- EXTREME WATER LEVEL FLUCTUATIONS
- CAMP SITE LICENSE TERMS

Turners Falls Project No. 1889-081

Northfield Mountain Pumped Storage Project No. 2485-063

Dear Commission,

I represent the people of the River Residents Association, as well as being a member. I own a cottage within the Project Lands, on the Horse Race section of the Connecticut River in Montague Massachusetts.

The Association is comprised of people who own camps, cottages, and homes along the river. There are 24 "licensed" sites on project lands, and, there are also private land owners, and members of private clubs that recreate on the Connecticut River within the Turners Falls/Northfield MA section of the river.

We are concerned for the future of this beautiful natural resource, as well as our existence along the rivers banks. We take exception to it being called the "lower reservoir" of the Northfield Mountain Pumped Storage project.

As many of us live on the river, we see things changing, sometimes on a daily basis.

Our major concern is the negative effects we see occurring from extreme erratic water level fluctuations.

The following are observations by people who live and recreate along the river. Many of us have spent decades here.

RECEIVED
 FEDERAL ENERGY REGULATORY COMMISSION
 2013 FEB 28 A 11:00
 2013 FEB 28

Page 2 of 4 – River Residents Association

Observations included but not limited to -

- erosion along the shores
- loss of recreation areas that allowed boat access, now have no shoreline, only steep banks to climb
- lack of adequate tenting facilities
- silt and sediment buildup
- sand bars that come and go
- algae growth in Barton Cove
- damage to personal property at “low tides” – torque damage to docks, boats stranded rocks/stuck in mud
- wetland/cattail/marsh habitat changing/vanishing
- land mass loss to islands
- sand bank habitat and swallows gone
- beaches appear and disappear within hours
- backwaters/shallows/coves depths diminishing
- less heron, osprey and kingfisher sightings
- less dragonflies seen
- changes in fishing bounty
- Fish egg nests exposed at “low tides” drying out and dying
- Waterfowl breeding grounds unexpectedly become submerged and eggs rot or offspring drown

We believe everyone here wants to work together to ask the right questions and find effective solutions. We feel we, the river residents, are an integral part of this process.

Is there a way to create moderation, or eliminate altogether, dramatic water level fluctuations? Can it be, should it be, regulated differently? For the record, the Association strongly favors research into a “closed loop” system. It would be a true man-made reservoir that would no longer involve the river for the generation of electricity.

We have prepared a visual exhibit. We hope it will enlighten, and underscore some of the concerning observations we have stated.

Our other concern is about our continued existence as residents along the river. Most of us in this association are “Camp” owners with a “License” agreement allowing us to occupy the land.

Our existing structures are a historical use that began back in the early 1920's and the previous licensees for these projects issued permits to manage their use. However, prior to 2008, the previous licensors did not seek Commission approval of these uses and occupancies of project property. Someone dropped the ball along the way. We owe great thanks to Mr. John Howard of the Northfield Mountain Pumped Storage facility for noticing this oversight. He realized there was no mention of the existing residential and private structures and took action to correct this. An application was filed in October

Page 3 of 4 – River Residents Association

2008, requesting Commission authorization to issue revocable 5-year licenses, as well as, life-use licenses (permits) for us on lands at the Northfield Mountain and Turners Falls

Hydroelectric Projects (FERC Project Nos. 2485-050 and 1889-069). The Commission granted an ORDER MODIFYING AND APPROVING NON-PROJECT USE OF PROJECT LANDS AND WATERS. It was issued October 28, 2009.

As licensees, we are mandated to do certain things, inspected once every year and be “in compliance” with the terms FirstLight Hydro Generating Company sets forth. As you can imagine, it’s unsettling to not know if all our love, sweat and money spent on our river homes will be for naught at the end of a 5-year license. The power company reaps many rewards using the river to generate power. For nearly 100 years our families have lived and recreated on this stretch of the river. My grandchildren are the 5th generation to grow up at our cottage, learning to swim in this river, fostering a love and respect for the natural world provided by this incredible watershed. We see ourselves as assets to this majestic waterway, and yet we have no reassurance that we’ll have any future past 5 years. It’s a very one sided situation and tenuous position to be in.

We act as caretakers, we are self appointed “Stewards.” We are the eyes and ears of the woods and waters. We investigate smoke sightings in the woods and have aborted forest fires, provide shelter and rides to people in canoes caught in storms, tow boaters out of gas or with broken engines and props, rescue anglers and others who fall over board and can’t swim, rescue kayakers who flip during cold water months, pick up countless amounts of trash after the “weekend warriors,” assist novice boaters and escort weary paddlers, rescue women in labor off the water to get to hospital, and sadly, even help search for bodies.

As proprietors of our footprints, we take seriously the investment in our lifestyle on the Connecticut River, both financially and emotionally. The majority of us have remodeled and made improvements to our properties. We have taken great pride in bettering our environments. We have given gladly and are gifted by the beauty, serenity and solitude the river offers. We delight in her recreational diversity. We celebrate family and friends, generation after generation. And, we continue on year after year in blind faith, that our 5-year licenses will be renewed. Does this seem equitable?

We realize we make the assumption that you, the Federal Energy Regulatory Commission and FirstLight Hydro Generating Company, want us to remain on project lands. It would be nice to know how you actually view us. What laws, if any, protect our interests?

We’d like a clearer understanding of how the licenses are administered. We’ve been under the impression that FERC governs over the use of the lands. However, according to the language in the “Order” approving use of project lands dated October 2009, it appears that FirstLight Hydro Generation Company makes the decisions governing us, the licensor’s. Does FERC have any say in our interests? Is there a liaison within the FERC organization that can work with our Association in helping us better understand our rights

Page 4 of 4 – River Residents Association

and responsibilities? How can we alter the current arrangement to meet our present and future needs?

We respectfully ask for consideration in lengthening the license term commensurate to the number of years approved for FirstLight Hydro Generation Company's new license to operate beginning in 2018. What is the procedure to effectuate this?

We endeavor to continue to assist and promote an ongoing cooperative relationship with all parties interest in mind. We are dedicated to a life worth living on a river worth loving. We thank you for your time and respectfully submit this inquiry and photographs to the Commission.

Sincerely,

**Leena Newcomb

RE: Connecticut River concerns -

- EXTREME WATER LEVEL FLUCTUATIONS
- CAMP SITE LICENSE TERMS

Turners Falls Project No. 1889-081
Northfield Mountain Pumped Storage Project No. 2485-063

Dear Commission,

Michael and Diane Kane
Camp 10E - West Camp Road
Montague, MA 01351

I am a member of The River Residents Association. The Association is comprised of people who own camps, cottages, and homes along the river. There are 24 "licensed" sites on project lands, and, there are also private land owners, and members of private clubs that recreate on the Connecticut River within the Turners Falls/Northfield MA section of the river.

We are concerned for the future of this beautiful natural resource, as well as our existence along the rivers banks. We take exception to it being called the "lower reservoir" of the Northfield Mountain Pumped Storage project.

As many of us live on the river, we see things changing, sometimes on a daily basis.

Our major concern is the negative effects we see occurring from extreme erratic water level fluctuations.

The following are observations by people who live and recreate along the river. Many of us have spent decades here.

Page 2 of 4 – River Residents Association

Observations included but not limited to -

- erosion along the shores
- loss of recreation areas that allowed boat access, now have no shoreline, only steep banks to climb
- lack of adequate tenting facilities
- silt and sediment buildup
- sand bars that come and go
- algae growth in Barton Cove
- damage to personal property at “low tides” – torque damage to docks, boats stranded rocks/stuck in mud
- wetland/cattail/marsh habitat changing/vanishing
- land mass loss to islands
- sand bank habitat and swallows gone
- beaches appear and disappear within hours
- backwaters/shallows/coves depths diminishing
- less heron, osprey and kingfisher sightings
- less dragonflies seen
- changes in fishing bounty
- Fish egg nests exposed at “low tides” drying out and dying
- Waterfowl breeding grounds unexpectedly become submerged and eggs rot or offspring drown

We believe everyone here wants to work together to ask the right questions and find effective solutions. We feel we, the river residents, are an integral part of this process.

Is there a way to create moderation, or eliminate altogether, dramatic water level fluctuations? Can it be, should it be, regulated differently? For the record, the Association strongly favors research into a “closed loop” system. It would be a true man-made reservoir that would no longer involve the river for the generation of electricity.

We have prepared a visual exhibit. We hope it will enlighten, and underscore some of the concerning observations we have stated.

Our other concern is about our continued existence as residents along the river. Most of us in this association are “Camp” owners with a “License” agreement allowing us to occupy the land.

Our existing structures are a historical use that began back in the early 1920's and the previous licensees for these projects issued permits to manage their use. However, prior to 2008, the previous licensors did not seek Commission approval of these uses and occupancies of project property. Someone dropped the ball along the way. We owe great thanks to Mr. John Howard of the Northfield Mountain Pumped Storage facility for noticing this oversight. He realized there was no mention of the existing residential and private structures and took action to correct this. An application was filed in October

Page 4 of 4 – River Residents Association

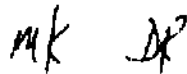

and responsibilities? How can we alter the current arrangement to meet our present and future needs?

We respectfully ask for consideration in lengthening the license term commensurate to the number of years approved for FirstLight Hydro Generation Company's new license to operate beginning in 2018. What is the procedure to effectuate this?

We endeavor to continue to assist and promote an ongoing cooperative relationship with all parties interest in mind. We are dedicated to a life worth living on a river worth loving. We thank you for your time and respectfully submit this inquiry and photographs to the Commission.

Sincerely,

Michael and Diane Kane

RE: Connecticut River concerns -

- EXTREME WATER LEVEL FLUCTUATIONS
- CAMPSITE LICENSE TERMS

Turners Falls Project No. 1889-081

Northfield Mountain Pumped Storage Project No. 2485-063

Dear Commission,

I have resided in Gill for 35 years and own 7 acres that abutt First Light's property, I own Camp #14W located at the corner of King Philip's Abyss and Horse Race and have a Life-Use License with First Light GDF Suez.

I am a member of The River Residents Association. The Association is comprised of people who own camps, cottages, and homes along the river. There are 24 "licensed" sites on project lands, and, there are also private land owners, and members of private clubs that recreate on the Connecticut River within the Turners Falls/Northfield MA section of the river.

We are concerned for the future of this beautiful natural resource, as well as our existence along the rivers banks. We take exception to it being called the "lower reservoir" of the Northfield Mountain Pumped Storage project.

As many of us live on the river, we see things changing, sometimes on a daily basis.

Our major concern is the negative effects we see occurring from extreme erratic water level fluctuations.

The following are observations by people who live and recreate along the river. Many of us have spent decades here.

116 V 9-5-11
REC'D
FEB 27 2013

Page 2 of 4 – River Residents Association

Observations included but not limited to -

- erosion along the shores
- loss of recreation areas that allowed boat access, now have no shoreline, only steep banks to climb
- lack of adequate tenting facilities
- silt and sediment buildup
- sand bars that come and go
- algae growth in Barton Cove
- damage to personal property at “low tides” – torque damage to docks, boats stranded rocks/stuck in mud
- wetland/cattail/marsh habitat changing/vanishing
- land mass loss to islands
- sand bank habitat and swallows gone
- beaches appear and disappear within hours
- backwaters/shallows/coves depths diminishing
- less heron, osprey and kingfisher sightings
- less dragonflies seen
- changes in fishing bounty
- Fish egg nests exposed at “low tides” drying out and dying
- Waterfowl breeding grounds unexpectedly become submerged and eggs rot or offspring drown

We believe everyone here wants to work together to ask the right questions and find effective solutions. We feel we, the river residents, are an integral part of this process.

Is there a way to create moderation, or eliminate altogether, dramatic water level fluctuations? Can it be, should it be, regulated differently? For the record, the Association strongly favors research into a “closed loop” system. It would be a true man-made reservoir that would no longer involve the river for the generation of electricity.

We have prepared a visual exhibit. We hope it will enlighten, and underscore some of the concerning observations we have stated.

Our other concern is about our continued existence as residents along the river. Most of us in this association are “Camp” owners with a “License” agreement allowing us to occupy the land.

Our existing structures are a historical use that began back in the early 1920's and the previous licensees for these projects issued permits to manage their use. However, prior to 2008, the previous licensors did not seek Commission approval of these uses and occupancies of project property. Someone dropped the ball along the way. Page 3 of 4 – River Residents Association

2008, requesting Commission authorization to issue revocable 5-year licenses, as well as, life-use licenses (permits) for us on lands at the Northfield Mountain and Turners Falls

Hydroelectric Projects (FERC Project Nos. 2485-050 and 1889-069). The Commission granted an ORDER MODIFYING AND APPROVING NON-PROJECT USE OF PROJECT LANDS AND WATERS. It was issued October 28, 2009.

As licensees, we are mandated to do certain things, inspected once every year and be “in compliance” with the terms First Light Hydro Generating Company sets forth. As you can imagine, it’s unsettling to not know if all our love, sweat and money spent on our river homes will be for naught at the end of a 5-year license.

The power company reaps many rewards using the river to generate power. For nearly 100 years our families have lived and recreated on this stretch of the river. We see ourselves as assets to this majestic waterway, and yet we have no reassurance that we’ll have any future past 5 years. It’s a very one sided situation and tenuous position to be in.

We act as caretakers, we are self appointed “Stewards.” We are the eyes and ears of the woods and waters. We investigate smoke sightings in the woods and have aborted forest fires, provide shelter and rides to people in canoes caught in storms, tow boaters out of gas or with broken engines and props, rescue anglers and others who fall over board and can’t swim, rescue kayakers who flip during cold water months, pick up countless amounts of trash after the “weekend warriors,” assist novice boaters and escort weary paddlers, rescue women in labor off the water to get to hospital, and sadly, even help search for bodies.

As proprietors of our footprints, we take seriously the investment in our lifestyle on the Connecticut River, both financially and emotionally. The majority of us have remodeled and made improvements to our properties. We have taken great pride in bettering our environments. We have given gladly and are gifted by the beauty, serenity and solitude the river offers. We delight in her recreational diversity. We celebrate family and friends, generation after generation. And, we continue on year after year in blind faith, that our 5-year licenses will be renewed. Does this seem equitable?

We realize we make the assumption that you, the Federal Energy Regulatory Commission and First Light Hydro Generating Company, want us to remain on project lands. It would be nice to know how you actually view us. What laws, if any, protect our interests?

We’d like a clearer understanding of how the licenses are administered. We’ve been under the impression that FERC governs over the use of the lands. However, according to the language in the “Order” approving use of project lands dated October 2009, it appears that First Light Hydro Generation Company makes the decisions governing us, the licensor’s. Does FERC have any say in our interests? Is there a liaison within the FERC organization that can work with our Association in helping us better understand our rights

Page 4 of 4 – River Residents Association

and responsibilities? How can we alter the current arrangement to meet our present and future needs?

We respectfully ask for consideration in lengthening the license term commensurate to the number of years approved for First Light Hydro Generation Company's new license to operate beginning in 2018. What is the procedure to effectuate this?

We endeavor to continue to assist and promote an ongoing cooperative relationship with all parties' interest in mind. We are dedicated to a life worth living on a river worth loving. We thank you for your time and respectfully submit this inquiry and photographs to the Commission.

United States of America
Federal Energy Regulatory Commission

Good day to the Commission,

My name is Leena Newcomb. I own a cottage on the "Horse Race" section of the river here on the Montague side.

I have been asked to speak on behalf of the River Residents Association. We are dedicated to preserving a life worth living on a river worth loving.

The Association is comprised of people who own camps, cottages, homes, and land, and also members of private clubs that recreate on the Connecticut River within the Turners Falls/Northfield MA section of the river.

We are concerned for the future of this beautiful natural resource, as well as our existence along the rivers banks.

As many of us live on the river, we see things changing, sometimes on a daily basis.

Our major concern is the negative effects we see occurring from extreme erratic water level fluctuations.

The following are observations by people who live and recreate along the river. Many of us have spent decades here.

Observations included but not limited to:

- shifts in the shoreline and river bed
- erosion along the shores
- loss of recreation areas that allowed boat access, now have no shoreline, only steep banks to climb
- lack of adequate tenting facilities
- silt and sediment buildup
- sand bars that come and go
- algae growth in Barton Cove
- damage to personal property at "low tides" – torque damage to docks, boats stranded on rocks/stuck in mud

REGULATORY COMMISSION

2013 FEB 28 P 2:21
2013 Feb 28

SECRETARY OF ENERGY
COMMISSION

- wetland/cattail marsh habitat changing/vanishing
- land mass loss to islands
- sand banks and swallows gone
- beaches appear and disappear within hours
- backwaters/shallows/coves depths diminishing
- less heron, osprey and kingfisher sightings
- less dragonflies seen
- changes in fishing bounty
- Fish egg nests exposed at "low tides" drying out and dying
- Birds nesting grounds unexpectedly become submerged

We believe everyone here wants to work together to ask the right questions and find effective solutions. We feel we, the river residents, are an integral part of this process.

Is there a way to create moderation, or eliminate altogether, dramatic water level fluctuations? Can it be, should it be, regulated differently?

We have prepared a visual exhibit for you to keep. We hope it will enlighten, and underscore some of the concerning observations we have stated.

{exhibit shown}

Our other concern is about our continued existence as residents along the river. Most of us in this association are "Camp" owners with a "License" agreement allowing us to occupy the land.

Our existing structures are a historical use that began back in the early 1920's and the previous licensees for these projects issued permits to manage their use. However, prior to 2008, the previous licensors did not seek Commission approval of these uses and occupancies of project property. Someone dropped the ball along the way. We owe great thanks to Mr. John Howard of the Northfield Mountain Pumped Storage facility for noticing this oversight. RE: Connecticut River concerns -

- **EXTREME WATER LEVEL FLUCTUATIONS**
- **CAMPSITE LICENSE TERMS**

Turners Falls Project No. 1889-081
Northfield Mountain Pumped Storage Project No. 2485-063

Dear Commission,

Vivien Venskowski
Camp 8W – Trenholm Way
Gill, MA 01354

I am a member of The River Residents Association. The Association is comprised of people who own camps, cottages, and homes along the river. There are 24 “licensed” sites on project lands, and, there are also private land owners, and members of private clubs that recreate on the Connecticut River within the Turners Falls/Northfield MA section of the river.

My major concerns are listed as follows:

- **One major concern is the negative effects we see occurring from extreme erratic water level fluctuations.**
- **silt and sediment buildup**
- **how wildlife and habitat is effected by the instability of the river level (too much too little)**
- **erosion along the shores**
- **wetland/cattail/marsh habitat changing/vanishing**
- **vanishing sandy beaches**

Is there a way to create moderation, or eliminate altogether, dramatic water level fluctuations?

Another concern is about our continued existence as residents along the river. Most of us in this association are “Camp” owners with a “License” agreement allowing us to occupy the land.

We respectfully ask for consideration in lengthening the license term commensurate to the number of years approved for FirstLight Hydro Generation Company's new license to operate beginning in 2018. As licensees, we are mandated to do certain things, inspected once every year and be "in compliance" with the terms FirstLight Hydro Generating Company sets forth. **As you can imagine, it's unsettling to not know if all our love, sweat and money spent on our river homes will be for naught at the end of a 5-year license.** The power company reaps many rewards using the river to generate power. For nearly 100 years our families have lived and recreated on this stretch of the river. We act as caretakers, we are self-appointed "Stewards". We are the eyes and ears of the woods and waters. We investigate smoke sightings in the woods and have aborted forest fires, provide shelter and rides to people in canoes caught in storms, tow boaters out of gas or with broken engines and props, rescue anglers and others who fall over board and can't swim, rescue kayakers who flip during cold water months, pick up countless amounts of trash after the "weekend warriors," assist novice boaters, try to protect the wildlife, remove invasive plants and escort weary paddlers, rescue women in labor off the water to get to hospital, and sadly, even help search for bodies.

Thank you for your time.

Respectfully submitted,

Vivien Venskowski

Re: Application for re-licensing of the Northfield Mountain Pumped Storage Project (P-2485-063), the Vernon Project (P-1904-073) and the Turners Falls Project (P-1889-081)

Submitted by Jennifer Tufts, Member, Northfield Open Space Committee

Attached is a copy of the Survey Results Summary from the 2011 Open Space and Recreation Survey conducted by the Northfield Open Space Committee as part of the updating of the 2005 Open Space and Recreation Plan (OSRP). Also enclosed is a printed copy of table 9-1 'Recommended Action Steps to Implement the 2012 Northfield OSRP'.

The Open Space Committee has made it a priority to monitor the FERC re-licensing as part of its commitment to Coordination and Water resource oversight (see OS2.7 and OS6.5).

There is a wealth of information in the OSRP which we would commend to the FERC re-licensing team. The complete 2005 OSRP and the draft 2012 OSRP as well as more information on the extensive Survey process can be found at <http://www.northfield.ma.us/index.php?id=155>.

re: Northfield Mountain Pumped Storage Project

presented at FERC hearing at Turners Falls

Greetings,

We own the first privately owned parcel upstream (aprox. 1000 yards upstream) of the Northfield Mountain Pumped Storage Project. We have a verbal agreement with Chuck Momney of First Light for a repair of a previous repair of the Conn. River bank done in 1996. The promise is to do it this year or next.

If this agreement is not fulfilled as has happened in the past, we would like to reserve the right to bring it to your attention in the next couple years.

Sincerely,

Thomas R Shearer
Patricia E Shearer

Patricia E Shearer

FEDERAL ENERGY
REGULATORY COMMISSION

FEB 28 P 2:27

SECTION OF THE
COMMISSION

Present and Increased Noise Level Determination and (possible) Mitigation of Northfield Mountain Project

5.9(b)(1)--Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of this study is to evaluate the current level of noise produced by the Northfield Mountain Project as heard by neighbors to the project; to determine if the proposed changes to the project (including utilizing more storage in the upper reservoir and increasing the unit and station capacity) increase the noise level; and to mitigate any present and future noise.

Specifically, the objectives of the study include:

- * determine a baseline current noise level for the Northfield Mountain Project. Is the Northfield Mountain Project responsible for noises heard in the area?
- * determine if changes to the project increase the noise level
- * mitigate any existing and future noise levels

5.9(b)(2)--If applicable, explain the relevant resource management goals of the agencies of Indian tribes with jurisdiction over the resource to be studied.

Not applicable.

5.9(b)(3)--If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

It is in the public's interest that this project and its expansion not negatively impact the quality of life for Northfield Mountain Project's neighbors. Noise negatively impacts quality of life.

Background and Existing Information

5.9(b)(4)---Describe existing information concerning the subject of the study proposal, and the need for additional information.

According to Scoping Document 1 for Northfield Pump Storage Project, FERC No. 2485-063 B, no Aesthetic or Socioeconomic issues have been identified for this project. Noise levels are not only aesthetic, but also socioeconomic if they affect real estate values in the area immediately surrounding the project. Thus additional information is needed on this subject.

Project Nexus

5.9(b)(5)---Explain any nexus between project operations and effects (direct, indirect, and/or cumulative) on the resources to be studied, and how the study results would inform the development of license requirements.

Northfield Pump Storage Project runs pumps to move water to a holding reservoir, and turbines to harvest energy from the water. Both these operations involve large equipment that makes a lot of noise. This noise may be broadband, low frequency, or infrasonic pressure or vibration. Increasing the pump and/or turbine operation in frequency, size, or number could impact the amount of noise this equipment makes, so that it is more audible to neighbors. Noise might need to be mitigated e.g. via insulation, or prescribed combinations of equipment running, etc. to reduce noise impact on neighbors.

Proposed Methodology

5.9(b)(6)--Explain how any proposed study methodology (including any preferred data collection and analysis techniques or objectively quantified information, and a schedule including appropriate field season(s) and the duration is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

Massachusetts Department of Environmental Protection recognizes noise pollution: "Noise is a public health concern that falls within the scope of Massachusetts Department of Environmental Protection (MassDEP) authority as a form of regulated air pollution (M.G.L. Chapter 111, Sections 142A-M provide statutory authority for MassDEPs Air Pollution Control Regulations, 310 CMR 7.00" (<http://www.mass.gov/dep/air/laws/noisepol.htm>, accessed 1/31/13)

We propose to use MassDEP testing standards, should the noise need testing. Tests for infrasonic pressure or vibration should be included as well, where standards exist.

To simplify the process and possibly eliminate unnecessary tests, we propose a 2-part process: Part A to determine if the unexplained noises heard in the area are caused by the Mountain, and Part B using DEP protocol to determine how loud the noises are and if mitigation is called for. Mitigation would follow as needed. Each of these parts would need to be conducted before and after any change in the project (increased capacity etc).

Proposed methods include:

Part A: (1 year)

- * Having neighbors to the project record unexplained noises including what type of noise and when.
- * Comparing these lists with operating records of the Northfield Mountain Project to see if correlation exists.

Part B: (1 year)

- * If correlation exists, further study would be needed using MassDEP protocols. This part could be done simultaneously with Part A to increase turn-around time, or left until afterwards on the chance it would not be needed. It could also be the first step in the process if Part A was not considered necessary.

Level of Effort and Cost

5.9(b)(7)--Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs

The estimated cost of determining a baseline noise level and comparing any old/new noises with the operating records is relatively low. Possibly there is already a community liaison from Northfield Mountain who could interface with neighbors, leaving only the cost of printing out existing operations records over a 1 year period to take into account tree leafing and other seasonal changes. Estimate: less than \$500.

If it is determined that the Northfield Mountain Project is making noise (either now or after installation of further equipment), then the cost of measuring the noise level would include hiring qualified engineers to do so, possibly tens of thousands of dollars. Mitigating the noise would be even more expensive, include hiring qualified engineers and installing noise mitigation equipment, likely several hundred thousand dollars.

Since there are no proposed alternative studies, it is unknown if any would meet the stated information needs.

Board of Selectmen
Town of Montague

Turners Falls, MA 01376 (413) 863-3200 xt. 110
FAX: (413) 863-3231

February 6, 2013

Mr. Robert Quiggle, RPA
HDR Engineering Inc.
1304 Buckley Road
Suite 202
Syracuse, NY 13212-4311

Hello Robert:

We met at the FERC Relicensing Hearing in Turners Falls last week. I promised that I would send you a copy of the National Register Eligibility Notification for the Turners Falls Ceremonial Site and my concept paper for the Great Falls Native Cultural Park.

The Town of Montague is particularly interested in having this information seriously considered during the relicensing process. This would include the importance of providing access to the area immediately below the Turners Falls dam, with the area developed as a native cultural park. Other possible areas of interest are the Cabot Woods area which has potential for development of interpretive and educational features.

I would appreciate hearing your feedback with respect to the potential for incorporating our plans into the licensing process.

Frank Abbondanzio
Town Administrator

Landowners and Concerned Citizens for License Compliance

RE: Relicensing of the Northfield Mountain Pumped Storage Project (FERC No. 2485-063 and the Turners Falls project (FERC no. 1889-08
Comments on the Preliminary Application Document, Scoping Document 1, and
Study Requests

Dear Secretary Bose:

The Landowners and Concerned Citizens for License Compliance consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion. It has been said during the relicensing process that mitigation strategies must await studies to determine the causes of erosion. This is an old discussion that seemed to be resolved decades ago with licensee acknowledgement that much of the erosion problems are a result of project operations.

Some of our members filed a letter to the FERC Secretary on May 16, 2008 documenting landowner concerns having been continuous since 1972, starting with letters to the then Federal Power Commission (FPC). This filing also contained a chronology by previous landowners of thirty-five years of advocacy by concerned landowners and public agencies, that began with the activation of Northfield Mountain Pumped Storage Project in 1972, to address streambank erosion on the Connecticut River.

This chronology excerpts a July 12, 1976 Northeast Utilities letter to the FPC stating that: "Early in the planning stages of the Northfield Project, it was recognized that increased fluctuations on water levels in the Turners Falls Pond would cause damage to trees along the river's edge....Since the initial operation of the Project in late 1972, Northeast Utilities has been aware of bank erosion and has been monitoring a number of these areas along the pond."

A similar viewpoint is contained in the March 1977 "Streambank Erosion Control Evaluation and Demonstration Projects (Section 32) in New England," Haverhill, New Hampshire and Northfield, Massachusetts by the Department of the Army, New England

Division, Corps of Engineers, Waltham, Mass. It states on page 16: “Northeast Utilities (NU) constructed a pump-storage electric facility at Northfield Mountain which uses the Turners Falls pool as the lower impoundment. Turners Falls pool was raised 5.5 feet in 1973 and this area is one of the most actively eroding reaches of the Connecticut River today. The Corps has submitted a project proposal within the pool for construction under Section 32. NU acknowledges that much of the problem is a result of power pool operations.”

The LCCLC has been and continues to be concerned with the frequent and significant water level fluctuation associated with the operation of the Northfield Mountain Pumped Storage and Turners Falls projects, which result in streambank erosion and impacts to water quality, threatened and endangered species, fisheries, and riparian and littoral habitat. In particular, we believe that the Northfield Mountain Pumped Storage project and its operational use of the Connecticut River have been a long-term experiment that has resulted in significant adverse environmental impacts. We now have an opportunity to seriously consider the benefits of halting the use of the Connecticut River as the lower reservoir and creating a closed-loop lower reservoir which would address most of the environmental impacts and specific resource concerns raised by Federal and state agencies and stakeholders.

The LCCLC presented a photographic record of the erosion just upstream and across from the tailrace to the assembled FERC staff at the Scoping Meeting on January 30, 2013. Our scoping meeting presentation demonstrated why the current and previous owners of this conservation land have been so persistent in drawing FERC’s attention to the severity of erosion of our riverbanks and why the current restoration effort is several decades too late. In 1960 an Oak tree on the featured riverbanks stood approximately 30’ from the top edge of the bank. It is now less than 6’ from the top edge of the heavily eroded bank. This tree marks the site of Cross Section 8A that has been used by the Licensees over the years to monitor erosion in the Turners Falls Pool on the Connecticut River. So, quantitative data should be available to document this erosion, which we have previously placed in an information request to FERC.

Preliminary Application Document (PAD)

The 2008 Full River Reconnaissance (FRR) stated that the rate of erosion is decreasing in the Turners Falls Pool in the Connecticut River, which FirstLight continues to maintain in Section 4.2.4.1 of the PAD under FRR Studies. This contention is in spite of numerous challenges by the Connecticut River Streambank Erosion Committee (CRSEC) and professional studies commissioned by LCCLC, all of which have been filed with FERC and made a part of the licensing proceeding.

For reasons articulated in previous correspondence with FERC, we are concerned with the applicant’s plan to use information from the earlier Full River Reconnaissance (FRR) studies (2001, 2004 and 2008) and the Riverbank Erosion Comparison along the Connecticut River (2012) report, which the applicant updated to PAD 5.2.1 at the Scoping Meeting. We are currently working with the applicant and the Connecticut

River Streambank Erosion Committee to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR. This initiative and an outline for a Hydrologic, Hydraulic, and Geomorphic Analysis of Erosion in the Turners Falls Impoundment were also added to the PAD 5.2.1 at the Scoping Meeting. However, the Erosion Study has not been shared so the CRSEC and the LCCLC are not able to provide specific comments other than we hope that the findings and recommendations for further study found in detail in the 2007 Field Geology Services report, cited but only selectively referenced in PAD 4.2.4.3, are reflected in the proposed study.

We appreciate the opportunity to submit our comments on the Preliminary Application Document (PAD), Scoping Document 1, and eight Study Requests. Study Requests that we support are summarized by Scoping Document 1 resource areas. The full narratives of the studies that we are requesting to be undertaken may be found in the Appendix.

Scoping Document 1

3.5 Alternatives to the Proposed Action

On page 8 of the Scoping Document, the text reads that “[i]n accordance with NEPA, the environmental analysis will consider the following alternatives, at a minimum: (1) the no-action alternative, (2) the applicant’s proposed action, and (3) alternatives to the proposed action.” The LCCLC strongly urges the FERC staff to consider a closed-loop alternative for the lower reservoir serving the pumped storage project and requests that the applicant complete a study of this alternative to the proposed action.

6.0 Request for Information and Studies (See Appendix for full Studies)

Geology and Soil Resources

The LCCLC is primarily concerned with the various effects of erosion of the riverbanks in the Turners Falls Pool. With this in mind, we request that the 1999 Erosion Control Plan for the Turners Falls Pool of the Connecticut River be continued and a Full River Reconnaissance be conducted every 3-5 years with improved methodology that is documented with a Quality Assurance Project Plan. Our concerns relate to the environmental effects of the frequent and significant water level fluctuations and river flow dynamics resulting from the operation of the Northfield Mountain Pump Storage Project and the Turners Falls Dam. These concerns include riverbank stability, shoreline habitat, farmland, wetlands, riparian and littoral habitat, and water quality. We request that the following studies be conducted to address our concerns on these issues: (Full narratives are to be found in the Appendix.)

- **Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage (NMPS) Operations. (See Study Request #1a)**
- **Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River (#2a)**

- **Study of the Feasibility of Converting the Northfield Mountain Pumped Storage (NMPS) Facility to a Closed-loop or Partially Closed-loop System (#3a)**
- **Study Climate Change as it Relates to Continued Operation of Northfield Mountain Pumped Storage and Turners Falls Projects (#4a)**

Water Resources

Many residents in the Turners Falls Pool are riverside dwellers and express on-going concern for what they observe happening to the River on a daily basis. Residents report that swimming and boating have become increasingly unpleasant, and at times water levels are so low as to ground boats. Our River has historically provided diverse recreational opportunities with benefits to our regional economy. The Town of Gill's 2011 Open Space and Recreation Plan Public Survey results, on recreational use by Town residents, show that 90% of the respondents use the Connecticut River and Barton Cove for recreation at least yearly. With this in mind, the LCCLC wishes to explore levels of turbidity and suspended sediment in the river and what fluctuations in the water levels might have on the spread of exotic and invasive species, such as water chestnuts, and thus requests the following studies:

- **Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River (#2a)**
- **Water Quality Monitoring in the Turners Falls Impoundment and Downstream of the Turners Falls Project (#5a)**
- **Quantify the Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation Including Invasive Species and their Associated Habitats in the Turners Falls Dam project Impoundment (#6a)**
- **Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations (#8a)**

Socioeconomic Resources

The loss of agricultural and conservation land from soil erosion and the impact of the Turners Falls Dam on recreational use of the river are two major impacts on the socioeconomic resources from the Projects. The LCCLC is increasingly aware of the costs of the two Projects to the riverbanks, the habitat and water quality. The relicensing process is a once-in-a-lifetime opportunity to ensure that impacts on these areas are fully understood and defined, and that subsequent relevant resource management goals and public interest considerations are effectively addressed.

Consideration of all possible solutions to these questions is in order, from investigating a full-closed loop system to any number of partial-loop systems, thereby eliminating some of the negative consequences.

With this in mind we request:

- **Study of the Feasibility of Converting the Northfield Mountain Pumped Storage (NMPS) Facility to a Closed-loop or Partially Closed-loop System (#3a)**
- **Study Climate Change as it Relates to Continued Operation of the Vernon, Bellows Falls, Wilder, Northfield Mountain Pumped Storage, and Turners Falls Projects (#4a)**

Aquatic Resources

The LCCLC wishes to conserve, protect, and enhance habitats for fish, wildlife, and plants. The fact that land directly across from the NMPS tailrace (the old Stacey's Ferry Landing) and upstream has been eroding since the project went into operation, serves to heighten our concern that Project operations negatively affect resident and migratory fish species.

With this the mind we request the following studies:

- **Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation Including Invasive Species and their Associated Habitats in the Turners Falls Dam Project Impoundment (#6a)**
- **Model Flows in the Northfield Mountain Pumped Storage Project Discharge Tailrace and Connecticut River 1 Kilometer Upstream and Downstream of the Discharge Using Two-Dimensional Computational Fluid Dynamics (CFD) Model Techniques (#7a)**
- **Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations (#8a)**

We appreciate the opportunity to provide comments on the PAD, Scoping Document 1, and to submit Study Requests. We look forward to continuing our active engagement in the relicensing of the Connecticut River projects.

Respectfully Submitted,

Landowners and Concerned Citizens for License Compliance - Study Requests

Numerical listing of Study Requests with full Studies to follow:

Study Request 1a: Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage (NMPS) Operations.

Study Request 2a: Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River

Study Request 3s: Study of the Feasibility of Converting the Northfield Mountain Pumped Storage (NMPS) Facility to a Closed-loop or Partially Closed-loop System

Study Request 4a: Study Climate Change as it Relates to Continued Operation of the Vernon, Bellows Falls, Wilder, Northfield Mountain Pumped Storage, and Turners Falls Projects

Study Request 5a: Water Quality Monitoring in the Turners Falls Impoundment and Downstream of the Turners Falls Project

Study Request 6a: Quantify the Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation Including Invasive Species and their Associated Habitats in the Turners Falls Dam project Impoundment

Study Request 7a: Model Flows in the Northfield Mountain Pumped Storage Project Discharge Tailrace and Connecticut River 1 Kilometer Upstream and Downstream of the Discharge Using Two-Dimensional Computational Fluid Dynamics (CFD) Model Techniques

Study Request 8a: Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations

Study Request 1a - Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage (NMPS) Operations

Development of the current configuration of the Northfield Mountain Pumped Storage project included raising the dam height at Turners Falls by 5.9 feet in 1970 in preparation for NMPS operations. Operations began in 1972; since then all project operations have operated under this raised dam environment. The additional 5.9 foot in elevation changed the elevation of the Turners Falls impoundment, which extends some 20 miles upstream. The increase in river elevation also resulted in motorized boat traffic becoming more popular and makes the use of larger boats more possible. The presence of motorized recreational boats increases wake energy that can accelerate bank erosion rates.

The operation of NMPS causes alterations to the river as a direct feature of plant functionality. The alterations include: 1) daily fluctuating pond levels which at times in some places can exceed six feet (the license allows fluctuations up to 9 feet measured at an undisclosed location near and upstream of the Turners Falls dam), 2) altered flow and velocity profiles of river and 3) changes to the downstream hydrograph. Elevation data for the river in Appendix E of the PAD indicate that stage changes of 2 to 3 feet during the summer of 2012 were not uncommon.

Raising the level of the river can saturate bank soils. These same soils can quickly become dewatered when the river is lowered by the NMPS pumping cycle. Repeated saturation and dewatering of banks can lead to bank instability which in turn can lead to bank failure and eroded material entering the river. See Field (2007)¹ for an extended discussion on bank erosion and failure mechanics. Elevated levels of turbidity and suspended solids in the water column can diminish rearing and migratory habitat for fish. When too much fine grain material is deposited on channel bed substrates, particularly those substrates used for spawning, spawning success of resident and migratory fish is compromised, potentially reducing recruitment and carrying capacity.

Goals and Objectives

The goals of this study request would be to determine the environmental effects of the presence and operation of the licensed facilities on river bank stability, shoreline habitat, agricultural farmland, wetland resources, bed substrate, and water quality in the Turners Falls impoundment. We recognize that data from other studies will be made available and we think that the data from these other studies could be used to help meet the objectives of this study request.

Objectives of the study include the following:

1. Calculate the total volume of eroded material, calculate resulting nutrient loading of eroded material, and document and describe the three dimensional changes to

¹ Field Geology Services. (2007). *Fluvial geomorphology study of the Turners Falls Pool on the Connecticut River between Turners Falls, MA and Vernon, VT*. Prepared for Northfield Mountain Pumped Storage Project. Farmington, ME: Field Geology Services.

- the bank, including lateral bank recession, changes to bank slope, and the presence and subsequent inundation of pre-project beaches and shoreline since the Turners Falls Dam was raised and the Northfield Mountain Pumped Storage facility came on-line.
2. Document and describe the changes to banks upstream and downstream of riverbank restoration projects, including bank recession.
 3. Identify the changes that have occurred to bed substrate as a result of fine grain material being eroded from the banks and being deposited on the channel bed.

Relevant Resource Management Goals and Public Interest Considerations

Our management goal is to ensure high quality habitat for migratory diadromous fish. Shortnose sturgeon, American shad and American eel all require suitable spawning, rearing, migratory and foraging habitat. Eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turners Falls impoundment, the bypass reach and downstream of the Turners Falls project reduces the quality of habitat for these species. Elevated levels of suspended sediment are associated with a diminution in water quality which also affects the quality of habitat encountered by trust resource species.

In addition to habitat effects, soil erosion contributes to nutrient loading. In 2001, the U.S. EPA approved New York and Connecticut's Long Island Sound (LIS) dissolved oxygen TMDL. As a result, the New England Interstate Water Pollution Control Commission (NEIWPCC) established the Connecticut River Workgroup and the Connecticut River Nitrogen Project. This project is a cooperative effort involving staff from NEIWPCC, the states of Connecticut, Massachusetts, New Hampshire, and Vermont, and EPA's Region 1 and Long Island Sound (LIS) offices. All are working together to develop scientifically-defensible nitrogen load allocations, as well as an implementation strategy, for the Connecticut River Basin in Massachusetts, New Hampshire, and Vermont that are consistent with TMDL allocations established for LIS. Since its inception, the Connecticut River Workgroup has participated in a number of projects to better understand nitrogen loading, transport, and reductions in erosion.

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to

carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information and Need for Additional Information

The PAD makes reference to several studies in section 4.2.4 including the Erosion Control Plan (Simons & Associates, 1999), previous Full River Reconnaissance studies (1998, 2001 – maps but no report generated, 2004, and 2008), Field Geology Services' 2007 fluvial geomorphic investigation of the Turners Fall impoundment, and 2012 investigations by Simons & Associates.

Field Geology Services' 2007 investigation provided several good recommendations for future work in section 9.3 of its report which, if implemented, could provide for: a) an improved understanding of the causes of erosion; b) more accurate monitoring of erosion; and c) more successful bank stabilization efforts. This document is a good point of reference. The Simons & Associates' (2012) documents are qualitative and based on several unstated assumptions that may not be valid. Full River Reconnaissance efforts have been undertaken using varying methodologies, making for difficult comparisons from one report to the other.

We believe that these existing studies do have data that can be useful if certain new analyses are undertaken. These analyses of existing data would help fill in our gaps of understanding of bank erosion in the Turners Fall impoundment. We are also asking for some additional field collected data. With the existing information, it should be possible to better display what changes have occurred to streambanks over time. Current Geographic Information System (GIS) software allows for various types of data to be assembled into a map and into a database such that change over time analysis can be conducted fairly easily. The change over time analysis is a critical analysis that is needed, and was already started under Field (2007).

Photos that have been taken at or near the same location but at different times exist. For example, the last three Full River Reconnaissance efforts have included continuous videotaping of the riverbanks with locational information. With these data, "snapshots" of the bank at various locations could be extracted and compared over time. Field (2007) photo locations could be re-shot as well. This existing information should be presented such that it is easy to discern where the photo was taken and what changes have occurred over time. A comparison of the bank every 100 ft could be compared over the years.

Historic aerial photography for the Turners Fall impoundment should be gathered and analyzed. Examples of good photographic datasets include the Field 2007 appendices and 1929 aerials. The location of the shoreline over time should be noted such that it is

easy to discern where bank retreat has been most severe and where the river has been relatively stable since the earliest aerial photograph was taken.

Very little turbidity data for the Turners Falls impoundment, the bypass reach or stretches of the Connecticut River downstream of the Turners Fall project exist. Thus far, implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) has yielded few results, and many technological difficulties (see *2012 Sediment Management Plan – 2012 Summary of Annual Monitoring* dated November 30, 2012). Suspended sediment monitoring equipment is installed at the Route 10 Bridge upstream of the project and inside the powerhouse, theoretically taking readings representative of pumping and discharging through the turbines. An analysis of how turbidity might change relative to rapidly changing impoundment levels would be very useful information.

Nexus to Project Operations and Effects

The construction of the NMPS project was contingent upon the Turners Falls project raising the dam crest elevation by 5.9 feet. The NMPS project operations rely on the Turners Falls impoundment as the source of water to be pumped up and then discharged back into the river through turbines. The importance of this river reach to the NMPS operation is made clear by FirstLight's reference to this portion of the river as the "lower reservoir." Daily pumping and discharging changes the ponded elevation of the Connecticut River which in turn leads to bank material that repeatedly becomes saturated and then dewatered. Weakened bank material can then become eroded and the fine grain material from the banks can enter the water column and be transported in suspension in the river and eventually settle onto bed material. The raising of the Turners Falls impoundment also made recreational boating more popular, including the introduction of large, high-horsepower powerboats that were not previously present. Because of the fluctuating water levels, boat wakes impact the shoreline to a much greater extent than would occur if levels were more constant, thus exacerbating both the effects of the wakes and the fluctuating levels. For these reasons, erosion caused or contributed by NMPS project operation can negatively affect spawning, rearing and migratory habitat for trust species and the endangered shortnose sturgeon. The requested study will help inform the Commission when contemplating mitigation measures and or operational modifications.

Proposed Methodology

1. This study should determine the net soil loss in cubic yards between 1970 and the present; a density estimate of the eroded material should also be provided. Provide an analysis of where the greatest loss has occurred, location of proximity to the tailrace, soil type, riparian land use, and vegetative cover in that area. Calculate nutrient loadings (nitrogen and phosphorus compounds) to the river system based on soil loss.
2. Obtain copies of the original survey plans for the project, and complete a new survey using the same landmarks used previously. The Field (2007) report states

- on page 11 that the original survey plans of the river are still retained by Ainsworth and Associates, Inc. of Greenfield MA. Use pre-operation aerial photos and current aerial photos to complete a 10-foot topographic map of the section of river between Turners Falls Dam and Vernon Dam and the 200-foot buffer regulated under the Massachusetts Rivers Protection Act. The Field (2007) report on page 11 states that Eastern Topographics, Inc. determined that sufficient information is known about the 1961 aerial photos (e.g., height of airplane) to create a 10-foot topographic map of that time period, and that 1961 aerial photos could be accurately overlaid with recent aerial photos. Field (2007) states that this analysis would enable a more reliable determination of small-scale shifts in channel position and changes in bank height that may have resulted from the erosion of a low bench that previously existed along portions of the river. Among other things, create a single map showing areas of erosion and deposition, and also overlay the Field report's hydraulic modeling analysis of the river channel.
3. With respect to the January 22, 2013 submittal from FirstLight to FERC regarding its long term monitoring transects in the Turners Fall impoundment, we ask that any data errors (as discussed in Field, 2007) and problems that have occurred over the years at each site be mentioned. We also ask that an analysis for each cross section extending to the top of the bank and including a portion of the floodplain be provided.
 4. Take the information presented in Figure 4.2.3-1 "Soils in the vicinity of Turners Falls and Northfield Mountain projects" in the PAD and convert from 63 categories to just a few that are defined in a key that will allow readers to understand which soils are easily erodible, which aren't, and where there is bedrock along the banks.
 5. Complete detailed surficial mapping (topographic map or LIDAR) to identify the various geomorphic surfaces, height of benches/terraces above the river level, and types of sediments underlying the surfaces. This will allow one to determine how erosion varies with geomorphic conditions. One could then normalize the amount of erosion to a specific type of bank material/geomorphic surface/terrace.
 6. Another information request covers the range of daily water level fluctuations. In this study request, we ask for an analysis on the degree to which boat wakes increase that fluctuation range. The task would be to observe boat wakes under a range of boat sizes and flow rates on the river. We recommend implementation of the 2007 Field report recommendation that states, "A more thorough study of boat waves is merited to better document how many boats use the Turners Falls Pool, how fast they travel, the type and size of waves they produce, and their impact on shoreline erosion."

A component of this study request is not necessarily for new data, but for existing data to be presented in a more clear, coherent and comprehensive manner. All existing photographs of banks that have been collected either by FirstLight, on behalf of FirstLight or on behalf of the Franklin Regional Council of Governments' (FRCOG) Streambank Erosion Committee should be georeferenced in such a way that it is easy to discern where the photograph was taken and the date should be easily discernible as well. These photos should be presented in a manner that makes it easy to visually see how a

particular section of bank has changed over time. Providing geographic context for photographic data of river banks and making these photos comparable over time should be standard practice. The 2007 Field report contains the following recommendation on page 47: “An attempt should be made to overlay the 1961 aerial photographs with a current flight and to create a topographic map from the 1961 flight. The feasibility of this effort has been confirmed by Eastern Topographics, Inc. This effort will identify the previous extent of the low bench and identify areas of the most significant bank recession the past 45 years.” Given that this statement was written in 2007, we request that that the analysis is extended to current conditions.

Given the complexity of this study request and the expertise necessary to implement it, we request that the FRCOG and the mandatory conditioning agencies be involved with the selection of the hired consultant.

Level of Effort and Cost

The level of effort to compile existing information and to make the data available in a map and searching for existing bed substrate material data should not take more than a few days. The level of effort for the bed sampling work will vary based upon how much existing historic information exists. Much of the effort of this study request is essentially office work that compiles and better presents existing data. While an estimate on the amount of field time required is difficult to make, we estimate that up to two weeks of field work could be required and that some of the data collection could be done while other field studies are occurring.

Study Request 2a – Study the Impact of Operations of the Northfield Mountain Pumped Storage Project and Turners Falls Dam on Sedimentation and Sediment Transport in the Connecticut River

Goals and Objectives

The goal of this study request is to provide hydraulic and sediment transport modeling of both the intake and discharge conditions (current and proposed) at the Northfield Mountain Pumped Storage Project. The results of the study should provide information sufficient to enable MA DEP staff and stakeholders to understand current and proposed effects on water level fluctuations and relate to potential increase in sedimentation to the Connecticut River. MA DEP staff and stakeholders should be able to identify techniques that could be used to mitigate the effects of project operations or other mitigation techniques that could be developed to reduce riverbank erosion within the impoundment. In addition, an assessment of means to minimize the sediment load passing through the Turners Falls Canal during and after maintenance drawdowns should be conducted.

The specific objectives of this study are as follows:

- Assess hydraulic and sediment dynamics in the Connecticut River from Vernon Dam to Turners Falls Dam, the upper reservoir at Northfield Mountain, and downstream of the Turners Falls Dam.
- Identify management measures to minimize erosion and sedimentation.
- Determine areas of sediment deposition and beach formation in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas, recreational uses and effects on invasive species, if any. Habitat areas include but are not limited to coves (e.g. Barton Cove), back channels, islands, wetland habitats, shorelines, shoals, deep water areas and channels.
- Identify management measures to mitigate for substrate (habitat) impacts and recreational impacts in sediment-starved areas below the dam and sediment accumulation areas upstream of the dam.

Relevant Resource Management Goals and Public Interest Considerations

The resource management goal is to ensure that the Connecticut River, which is designated as a Class B river for its entire length in Massachusetts, meets its designated uses of habitat for fish, other aquatic life and wildlife, and for primary and secondary contact recreation. Class B waters must also have consistently good aesthetic value and meet minimum criteria for numerous water quality indicators to achieve compliance with the standards set forth in the regulations. The other resource management goal is to protect prime farmland soils, which are eroding, and riparian habitat. Eco-based tourism

is important to the economy of Franklin County so maintaining the water quality of the river and protecting scenic landscapes along the river from erosion are important.

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information and Need for Additional Information

The PAD provides a summary of the work that has been done to characterize streambank conditions of the Turners Falls Impoundment, to understand the causes of erosion, and to identify the most appropriate approaches for bank stabilization. There has been no work undertaken to gather and assess the data that this study request would provide. Implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) was begun in 2011 and is scheduled to end in 2014. This is a limited study related to sediment problems in the upper reservoir, not the entire river.

Nexus to Project Operations and Effects

The Turners Falls and Northfield Mountain Pumped Storage projects operate in a peaking mode, with allowable impoundment fluctuations of up to 9 feet, with the intent to continue as such. It is proposed to evaluate increasing the volume of flow from the Northfield Mountain Pumped Storage Project through increased use of the upper reservoir, which is expected to result in additional water level fluctuations. Upstream hydroelectric facilities also operate in a peaking mode of operation. Periodically, the upper reservoir at Northfield Mountain and the power canal at the Turners Falls dam need

to be dewatered for maintenance purposes. Historically, both procedures have resulted in the discharge of large quantities of sediment. Sediment from shoreline erosion and riverbank failure is one of the major contributors that negatively affect water quality and habitat by increasing the turbidity and sedimentation, smothering aquatic habitat. Repetitive water level fluctuations and flow alterations caused by hydroelectric peaking operations are known to be a major contributor to shoreline erosion.

The Proposed Massachusetts Year 2012 Integrated List of Waters shows two river segments, from the VT/NH state line to the Turners Falls dam (MA34-01 & MA34-02) impaired and considered a “Water Requiring a TMDL” due to “Other flow regime alterations”, “Alteration in stream-side or littoral vegetative covers” and “PCB in Fish Tissue”. In addition, the segment below the Turners Falls dam to the confluence with the Deerfield River (MA34-03) is impaired by these causes as well as total suspended solids.

Proposed Methodology

We concur with the proposed methodology developed by the MA Department of Environmental Protection, which is consistent with accepted practices:

Assess hydraulic and sediment dynamics

- FirstLight to continue implementing the Northfield Mountain Pumped Storage Project Sedimentation Management Plan over the full range of river flows and pumping/generating cycles. An unfulfilled task in the Plan is to develop a correlation over the full range of flow conditions between the overall suspended sediment transport through the entire cross section of the river compared to the continuous sampling at the single fixed location. Environmental Protection Agency approval of a Quality Assurance Project Plan is required for valid data acquisition.
- Provide data on the daily water level fluctuation changes from the past five years from stations listed in the PAD, and estimate fluctuations within Turners Pool assuming proposed operations and hydraulic conditions.
- Identify the most appropriate techniques for bank stabilization given the existing and proposed hydraulic conditions.

Determine areas of sediment deposition in the Project Area

- Field (2007) conducted a bathymetric study as part of his report. Use previous bathymetric data, if available (Field 2007 recommends putting additional effort into finding a bathymetric survey from 1913 that was partially shown in Reid 1990), and current bathymetric information to look at areas of sediment accumulation. Determine areas of sediment deposition in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas. Habitat areas include but are not limited to coves (e.g., Barton Cove), back

channels, islands, wetland habitats, shorelines, shoals, deep water areas and channels.

- Identify recreational uses and impacts in areas known to be impacted by accumulated sediment, such as Barton Cove.
- Identify invasive species (plant or animal) present in the reaches and determine if erosion and sedimentation in any way contributes to the establishment and/or proliferation of these species.
 - Investigate the formation of beaches using remote sensing, LIDAR at low pool levels or some other mapping technique to understand the processes of beach deposition the distribution of beaches in the pool, the impact of beach deposition on habitat and species, and how can this be related to operation of NMPS.
 - Evaluate management strategies to address the release of accumulated sediment through Northfield Mountain Project works during upper reservoir drawdown or dewatering activities. FirstLight should specifically evaluate the feasibility of the installation of a physical barrier across the bottom of the intake channel designed to prevent the migration of sediment during future drawdowns of the upper reservoir
 - Evaluate management strategies to minimize flow fluctuations within Turners Pool including coordination with upstream users.
 - Evaluate management strategies to minimize sediment released through spillway gates and the log sluice located near the bottom of the forebay adjacent to the Cabot Powerhouse during canal dewatering activities.
 - Identify a prioritized list of locations for bank stabilization projects in the Project Area
 - Develop a map of land owned by FirstLight within 200 feet of the Connecticut River with an overlay of land use and vegetation cover. Provide land use options aimed at reducing bank erosion.

Management measures to change sediment flow below and above the dam.

- Any historic information of existing bed substrate material in the Turners Falls impoundment, bypass reach or downstream of the project should be collected and assembled. To the extent possible, the location of each sample should be made available on a map. The request for new data would stem from being able to make any valid comparison to changes in bed substrate at a given location, assuming the historic data exist.
- Identify measures that could be taken to mitigate impacts to recreational use, habitat, or invasive species from sedimentation.
- Identify measures that could be taken to change or mitigate sediment starved reaches below the Turners Falls dam.

Level of Effort and Cost

Many erosion studies have already been conducted and the cost of expanding the scope of some should be reasonable. A Full River Reconnaissance under the *Erosion Control Plan for the Turners Falls Pool of the Connecticut River* (Simons & Associates, Inc. dated

June 15, 1999) is scheduled for 2013 and could accomplish many of the objectives listed above.

Study Request 3a - Study the Feasibility of Converting the Northfield Mountain Pumped Storage (NMPS) Facility to a Closed-loop or Partially Closed-loop System

Building and operating the Northfield Mountain Pumped Storage project required the Turners Falls Dam be raised 5.9 feet. The Turners Falls impoundment of the Connecticut River acts as the lower reservoir and is subject to large sub-daily fluctuations in water level. The collateral environmental consequences of using the Connecticut River during the pumping and generation cycles for the last 40 years are not fully understood, but have likely contributed to extensive erosion of streambanks, downstream sedimentation, entrainment of large numbers of resident and migratory fishes, and destruction of important spawning and nursery habitat, both within the Turners Falls Pool and downstream. Intrinsic consequences include radical fluctuations in the hydrograph at a sub-daily level, which also negatively impact recreation, habitat, and likely disrupt key life history stages of resident and migratory fishes, benthic invertebrates, and macrophytes. The vast majority of proposed new pumped storage projects currently being considered by FERC are closed-loop because of a growing consensus that open-cycle pumped storage causes unacceptable environmental damage.

Resource agencies have identified restoration of a more natural hydrograph to the Connecticut River as a key management goal, and view the current relicensing process for five projects on the Connecticut River mainstem as an opportunity to achieve this. Converting to closed-loop or partial closed-loop would allow the restoration of ecological flows to the Connecticut River, and provide much greater flexibility in operational guidance for both NMPS and the other hydropower stations on the Connecticut River. It will also eliminate or partially eliminate many of the environmental concerns expressed by Federal and state agencies and other stakeholders, which are outlined in the numerous study requests and comment letters that FERC will receive on the NMPS project and the other four hydropower projects.

Goals and Objectives

The goal of this study request is to provide resource managers, stakeholders, and the licensee with an analysis of possible options for converting the plant to a close-loop or partially closed-loop system.

The objectives of this study request would be to determine:

- Candidate locations for placement of a lower reservoir
- Costs and logistics of construction and modification of the current facility to convert to a closed-loop or partially closed-loop system
- Projected savings associated with eliminating need for ongoing mitigation measures, both for stabilizing river banks as well as likely modification to operations that the facility that will be required to implement in order to protect habitat and native fauna.
- Other ancillary costs or savings, such as eliminating requested studies, operational changes, or mitigation measures

Relevant Resource Management Goals and Public Interest Considerations

The resource management goal is to ensure high quality habitat for migratory diadromous fish. Shortnose sturgeon, American shad, blueback herring, and American eel all require suitable spawning, rearing, migratory and foraging habitat. Eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turners Falls impoundment, the bypass reach and downstream of the Turners Falls project reduces the quality of habitat for these species. Elevated levels of suspended sediment are associated with a diminution in water quality that also affects the quality of habitat encountered by endangered species. Entrainment into the facility could be lethal to any of these fish. Juvenile and larval stages of resident and migratory species, including rare, threatened, and endangered species of vertebrates and invertebrates are particularly vulnerable to entrainment. This damage is aggravated by the repeated cycling of the facility—unlike standard hydro, where organisms are likely only exposed to passage events a single time and may bypass the system safely, NMPS continuously recycles river water, and therefore increases the risk of exposure to entrainment and death.

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information and Need for Additional Information

Some data on environmental effects of NMPS and facilities that use fresh or salt water for generation and/or cooling are widely available and consistently point to these types of facilities as damaging to native and migratory fauna. Once plentiful populations of blueback herring have been entirely eliminated from this portion of the Connecticut

River. Populations of American eel are in steep decline throughout this reach, and American shad that initially used fish passage facilities downstream of NMPS have experienced dramatic reductions above Turners Falls Dam.

Section 4.4.6 of the PAD (page 4-146) discusses entrainment at Northfield Mountain of migratory fish species. Previous studies estimated 28.6% of Atlantic salmon entrained, which was reduced to 6.7% after the installation of a guide net only during upstream passage season. LMS Engineers estimated in 1993 that the facility impacted 0 to 12.4% of adult American shad passing the water intake. No studies have looked at impacts to resident fish or other migratory fish or other times of the year, but several study request address this information gap.

Other facilities in the region (Brayton Point Power Station, a coal plant in Mt. Hope Bay) have been required by EPA to switch from open- to closed cycle at very significant cost because of the extensive damage done to fragile habitats by open-cycle pumping.

Streambank erosion has been a major concern since NMPS began operation in 1972. Section 4.2.4 of the PAD summarizes the extensive work that has been done to study and mitigate erosion along the river banks. Significant loss of agricultural land has resulted from unnatural river fluctuations and increased boat wakes from a raised impoundment, and in some cases poor mitigation efforts like helicopter removal of trees along the banks. Since 1996, the licensee has reportedly spent \$750,000 - \$1,000,000 annually on erosion control measures. In some cases, these projects will need to be re-done in the future. Converting the plant to closed-loop operation could provide significant cost savings over the life of the upcoming license, eliminating erosion control projects, proposed studies related to use of the Connecticut River as a lower reservoir, and any mitigation or operational changes that may be contemplated as a result of relicensing.

Nexus to Project Operations and Effects

In conjunction with other study requests, parties to the relicensing process will be reviewing data and considering operation and facility conditions that will best achieve the balance between natural resource protection, property and infrastructure protection, and power generation. Making the plant closed-loop or partially closed-loop is one important consideration to the scenario and would eliminate any operation changes that might result from concerns about fishery resources, water quality effects, and farmland losses.

Proposed Methodology

- Collate existing geological and hydrologic information of areas surrounding Northfield Mountain, including preliminary design plans for suitable facilities able to accommodate the existing and proposed discharge. These plans should include any and all possible locations, including modifications to infrastructure near the current outfall, and any other locations that could accommodate the necessary volume of water.

- Provide an engineering analysis of structural modifications necessary to accommodate a full or partial lower reservoir in an alternate nearby location.
- Provide information on whether and how a smaller lower reservoir, with ties to the Connecticut River, would act as a buffer to river level fluctuations and change the hydrologic pattern of flow on the Connecticut River in the Turners Falls pool (fluctuations), the water quality effects, and decrease the possibility of entrainment.
- Provide an analysis on water losses from evaporation and leakage and how much make-up water would be needed during normal operations by season or month.
- Identify and make available any similar studies conducted during the planning phase of the existing facility in the 1960's or any other time.
- Provide a cost estimate of each option considered and evaluated.
- Provide an itemized cost estimate of how halting the use of the Connecticut River as a lower reservoir would affect other costs, such as eliminating the erosion control program, any ancillary changes to generation at Turners Falls Dam and NMPS, and fish protection measures.

These methods are consistent with accepted practice for weighing costs and benefits of environmental impacts.

Level of Effort and Cost

The level of effort to compile existing information and to make the data available in a map should be low. Development of contingency scenarios would be low. The majority of the effort of this study request is essentially office work, with some engineering and design work required to scope likely costs of various scenarios.

Study Request 4a - Climate Change as it Relates to Continued Operation of the Vernon, Bellows Falls, Wilder, Northfield Mountain Pumped Storage, and Turners Falls Projects

Goals and Objectives

The goal of this study is to determine how climate change relates to the continued operation of the Vernon, Bellows Falls, Wilder, Northfield Mountain Pumped Storage, and Turners Falls projects.

The objectives of this study are:

1. Quantify the amount of thermal loading contributed by each respective impoundment (including the NMPS upper reservoir).
2. Using climate change prediction models, calculate how much warmer the project impoundments are projected to get in the next 30-50 years.
3. Model the effect of various project modifications on river temperature under current conditions and climate change predictions (e.g., converting to run-of-river, deep-water releases, dam removal, large-scale riparian revegetation, etc.).
4. Using climate change prediction models, determine if the projects actually provide an environmental benefit with respect to mitigating against climate change impacts (vis a vis warming of air and water temperatures) by producing low greenhouse gas emitting energy. The Northfield Mountain Pump Storage assessment must be based on net energy production (i.e., NMPS generates 1,143,038 MWh annually, but consumes 1,567,506 in its pumping operations; for a net consumption of 424,468 MWh annually).
5. Determine how climate change predictions will impact management of high flow events at the three projects and evaluate if changes to dam structures would mitigate adverse impacts of the existing flood management protocols.

Resource Management Goals

The Landowners and Concerned Citizens for License Compliance (LCCLC) supports the United State Fish and Wildlife Service' (Service) goals. The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to climate change, the Service's goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize deep headpond drawdowns associated with the loss of stanchion logs during high flow events, which are predicted to increase due to climate change.
3. Minimize project-related sources of thermal increases to Connecticut River waters to mitigate against predicted climate change impacts.

The Service, along with the National Oceanic and Atmospheric Administration (NOAA) and the Association of Fish and Wildlife Agencies developed a draft *National Fish, Wildlife and Plants Climate Adaptation Strategy* in 2012. The public comment period closed on March 5, 2012, and the agencies are working to finalize the document. Goal #7 of the Strategy calls for reducing non-climate stressors to help fish, wildlife, plants, and ecosystems adapt to a changing climate. The Strategy notes that some stressors (such as habitat loss and fragmentation and pollution) “are not only some of the things decision makers can control, they are also likely to interact with climate change to magnify negative impacts on fish, wildlife, and plants.”

Goal #7 contains a number of strategies and associated actions, including:

Strategy 7.1: Slow and reverse habitat loss and fragmentation

Actions:

- Consider application of offsite habitat banking linked to climate change habitat priorities as a tool to compensate for unavoidable onsite impacts and to promote habitat conservation or restoration in desirable locations
- Identify options for redesign and removal of existing structures/barriers where there is the greatest potential to restore natural processes.

Strategy 7.2: Slow, mitigate, and reverse where feasible ecosystem degradation from anthropogenic sources through...water resource planning, pollution abatement...

Actions:

- Work with water resource planners to identify potentially conflicting needs and opportunities to minimize ecosystem degradation resulting from development and land and water use.
- Reduce existing pollution and contaminants and increase monitoring of air and water pollution.
- Increase restoration, enhancement, and conservation of riparian zones and buffers in agricultural and urban areas to minimize non-point source pollution.

The Service’s study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Project.

Existing Information

The PADs contains no information relative to climate change and how climate change predictions may impact future operation of the hydroelectric plants, nor of how the projects either mitigate for or exacerbate predicted climate change impacts to freshwater ecosystems.

TransCanada's PADs provide a summary of water quality data collected in 2012. Table 1 below is a synthesis of the temperature data collected by TransCanada. It should be noted that the upper and mid-impoundment stations at each project represent the average of temperature readings taken over the entire water column, while the continuous loggers (Lower Cont. and TR) were located near the water surface. These data indicate that from the upstream end of the Wilder headpond to the Vernon tailrace, water temperature increased approximately 6°C.

Table 1. Median water temperature at monitoring stations located within the impoundments and tailraces of the three hydropower projects.

Project	Median Water Temperature °C			
	Upper Imp.	Mid-Imp.	Lower Cont.	TR
Wilder	20.86	21.83	24.08	23.59
BF	22.43	23.67	24.86	24.38
Vernon	23.81	24.49	26.73	26.35

Relative to existing flood management protocols at each station, TransCanada's PADs identify that all three dams utilize stanchion bays (two at Vernon, three at Bellows Falls, and four at Wilder). When inflows to each dam reach certain levels, the stanchion bays are removed, and cannot be replaced until inflows subside. The depth of these bays and the flows they are removed at are outlined in Table 2, below.

Table 2. Summary of pertinent stanchion bay Information for the Vernon, Bellows Falls, and Wilder projects.

Project	Stanchion Height (feet)	Flow Triggering Complete Stanchion Removal
Wilder	17	145,000 cfs
BF	13	50,000 cfs
Vernon	10	105,000 cfs

The PADs provide no information on the history of stanchion removal at any of the projects (frequency, duration, timing), nor a discussion of how predicted climate change might alter management of the stanchion bays in the future (with respect to the frequency and seasonality of occurrence). There also is no discussion of potential impacts to headpond resources that occurs as a result of stanchion bay removal. These information gaps need to be filled so resource agencies can assess the relative and cumulative impact of project operations with respect to the Service’s management goals and objectives, including those identified in the Climate Adaptation Strategy document.

Data provided by the National Oceanic and Atmospheric Administration, Climate Data Center, illustrates long-term increasing air temperatures in the Northeast (Figure 1). Long-term, monthly mean water temperature data for the Vernon Dam impoundment, monitored by Vermont Yankee, has shown significant differences over time (ANOVA analyses, $P < 0.05$) that when plotted and further analyzed by linear regression, show a significant increasing trend for the period 1974 – 2011 for the months of January, September, and October (Figure 2). These analyses were performed with data from Vermont Yankee, analyzed by the Massachusetts Department of Environmental Protection.

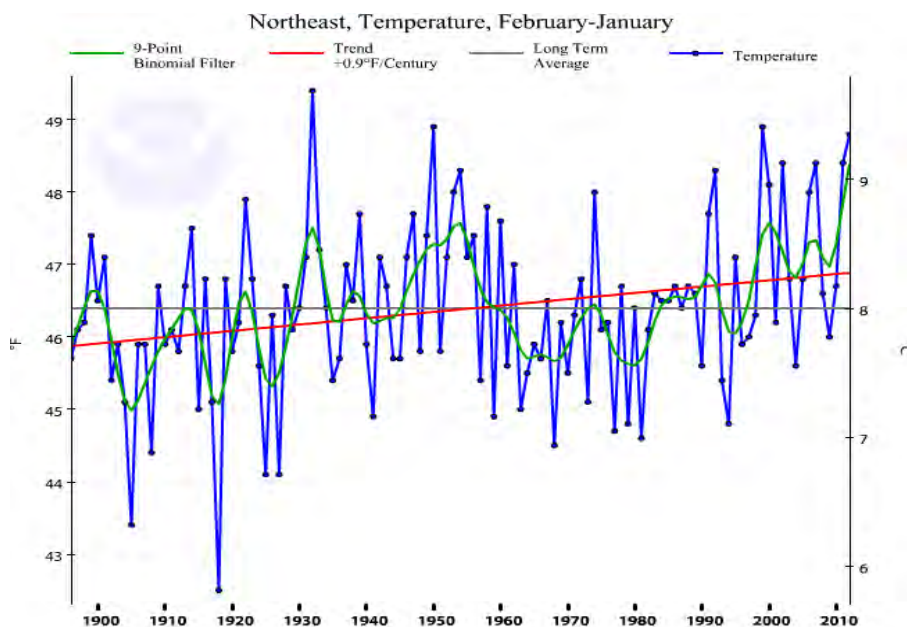

Figure 1. NOAA National Climate Data Center, Northeast 12-month average temperature for the period 1896 through 2012 (October).

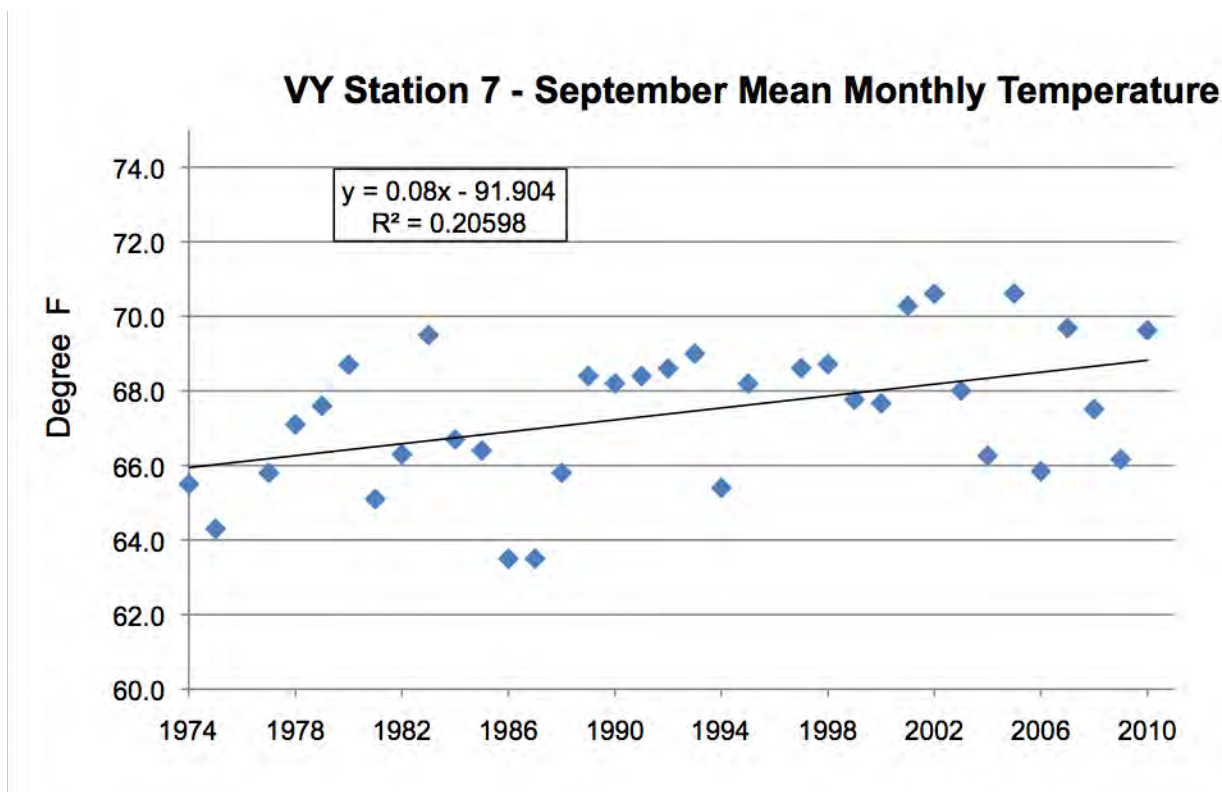

Figure 2. A plot of September’s mean temperatures for Vermont Yankees’ Station 7 (excludes outlier 1996 data point) for the period 1974 through 2011.

The PAD for Turners Falls and Northfield Mountain Pump Storage projects provides a summary of existing water quality data compiled by FirstLight, including water temperature data obtained from the Service. The PAD also notes a 1991 study by the former licensee that modeled thermal effects of pumping to the upper reservoir. That model reported a maximum temperature difference attributable to NMPS operation of 0.21°C in the Turners Falls reach of the Connecticut River in low flow (4,000 CFS) simulation.

Nexus to Project Operations and Effects

The four mainstem projects have very long impoundments capable of storing large volumes of water (Table 3, below). These impoundments effectively have converted large portions of the Connecticut River into a series of in-river “lakes.” Because water velocities slow in these impounded sections of river, it allows for increased thermal loading and resultant higher water surface temperatures than in free-flowing sections of river.

Table 3. Relevant characteristics of the reservoirs behind the Wilder, Bellows Falls, Vernon, Turners Falls dams and NMPS.

Project	Headpond Length (miles)	Gross Storage Volume (acre-ft.)	Average Depth (ft.)	Surface Area (acres)	Flushing Rate (days)
Wilder	45	34,350	11	3,100	3
BF	26	26,900	10	2,804	<2
Vernon	26	40,000	16	2,550	2
Turners	20	21,500		2,110	
NMPS	n.a.	17,,050		246	n.a.

Depending on where the hydropower intakes withdraw water, these warmer surface waters may be discharged downstream, raising the temperature of those waters as well (the data in Table 1 above suggest that the projects do draw water from the upper levels of the reservoirs). This effect may be felt for miles downstream. If there are a series of impoundments (like on the Connecticut River), the cumulative impact is an overall warming of the river. Even small run-of-river dams have been shown to elevate downstream water temperature (Lessard and Hayes 2003; Saila et al. 2005). The most recent climate change prediction models specific to the northeast forecast warmer air temperatures, more frequent high precipitation events, more heat waves, and an increase in the incidence of short term droughts (Karl et al. 2009).

Resource concerns related to this project effect include the potential impacts to populations (reductions in abundance, structure, condition) or loss of species not tolerant of increases in temperature and other effects related to physiology such as energetic costs with warmer temperatures (Leggett 2004). As one example, American shad restoration target numbers for fish passage at mainstem dams into upstream historic habitat could be negatively impacted from artificially increased water temperatures. Water temperature has been identified as a factor in the timing (i.e., duration) of this species migration, as well as its role in gonad development and spawning (Glebe and Leggett 1981; Leggett 2004). These factors can be logical reasoned to potentially result in accelerated rates of energy reserve use and a reduced migration window, possibly reducing the ability of fish to reach up-river habitats and further reducing the ability to survive downstream outmigration.

With respect to project operations during high flow events, all TransCanada projects have stanchion bays that are used to manage water during high flow events. Each time these stanchion bays are removed, the headponds are lowered substantially (from 10 to 17 feet, depending on the project) and must remain lowered until inflows subside. Depending on the timing and duration of these deep drawdowns, headpond resources could be negatively impacted.

All of the dams also contain other mechanisms for managing flows, such as tainter gates, sluice gates, roller gates, skimmer gates and hydraulic flood gates. All of these gates have an advantage over stanchion bays in that they do not require flows to subside significantly before they can be closed to return impoundment levels back to normal. One climate change prediction for the northeast is that we will see more frequent high

precipitation events which will result in high flow conditions on rivers. Therefore, it is likely that the stanchion bay removal protocol will have to be employed more frequently in the future.

Methodology Consistent with Accepted Practice

1. In order to quantify the amount of thermal loading contributed by each respective impoundment, detailed bathymetry will need to be collected. This bathymetry, combined with storage volume, tributary hydrology, and project operations, should be used to calculate the thermal loading of each headpond. The individual and cumulative increase in surface water temperature due to the impoundments should then be used to predict future warming based on climate change models.
2. Analyze different mitigation strategies to understand which have the greatest benefit in terms of building resilience against the impacts of climate change on water temperature. Potential scenarios to analyze include converting the projects to run-of-river, implementing deep-water releases, removing one or more dams, conducting large-scale riparian revegetation, etc.).
3. Input to climate change models the amount of GHG emissions that would be generated if fossil fuel plants were producing the equivalent amount of net energy as the five hydropower projects to determine the impact on air and surface water temperatures.
4. Climate change prediction model output should be assessed to determine if the frequency and timing of high flow events is likely to change in the future. If high flow events that necessitate initiating the stanchion bay removal protocol are predicted to increase in frequency and/or shift in timing, the applicant should evaluate structural and/or operational alternatives that would mitigate adverse impacts of the existing flood management protocols.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the thermal loading analysis would be low to moderate. Collecting bathymetry in the three TransCanada headponds would take two staff less than one week to collect (it took the Kansas Biological Survey two days to collect bathymetry at a 3,500 acre lake; Jakubauskas et al. 2011). Bathymetry for the Turners Falls pool and NMPS upper reservoir already exist. The remaining work would be desk-based; loading relevant information into an appropriate thermal loading model to compute the estimated thermal loading of each headpond and then comparing this information to surface water data from climate change prediction models.

The high flow flood protocol study is a desktop analysis that should require low cost and effort. Climate change models already exist and that output would be downloaded and analyzed. The remaining analysis requires a review of alternative means of managing flows without the use of stanchion bays.

The applicants did not propose any studies to meet this need in the PAD.

Study Request 5a - Water Quality Monitoring in the Turners Falls Impoundment and Downstream of the Turners Falls Project

Goals and Objectives

Determine the current water quality of the Connecticut River within the Turners Falls impoundment. The results of the study should provide information sufficient to enable mandatory conditioning agency staff to understand water quality conditions at the project. The study plan for the water quality monitoring should be developed in consultation with the U.S. Fish and Wildlife Service (USFWS) and the Massachusetts Department of Environmental Protection (MA DEP).

The specific objectives of this study are as follows:

- Characterize water quality in the Turners Falls impoundment, bypass reach, canal and below the confluence of the bypass reach and canal discharge.
- Evaluate the potential effects of project operation on water quality parameters such as temperature, dissolved oxygen, total suspended sediment and turbidity in conjunction with various other water uses.
- Determine the level of contamination in sediment impeded by Turners Falls dam.
- Collect continuous temperature, dissolved oxygen, total suspended sediment and turbidity data during the summer period and under various hydropower operating conditions at the Northfield Mountain Project.

Relevant Resource Management Goals and Public Interest Considerations

The resource management goal is to ensure that the Connecticut River, which is designated as a Class B river for its entire length in Massachusetts, meets its designated uses of habitat for fish, other aquatic life and wildlife, and for primary and secondary contact recreation. Class B waters must also have consistently good aesthetic value and meet minimum criteria for numerous water quality indicators to achieve compliance with the standards set forth in the regulations. The other resource management goal is to protect prime farmland soils, which are eroding, and riparian habitat. Eco-based tourism is important to the economy of Franklin County so maintaining the water quality of the river for boaters and kayakers is important, too.

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC,

including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information and Need for Additional Information

The PAD provides a summary of existing water quality data. While a number of monitoring efforts have taken place and include sample sites within the project boundary, none of those studies was designed to comprehensively investigate whether all relevant project areas currently meet Class B standards: The Massachusetts DEP's Connecticut River watershed assessment monitoring occurred in 2003, it had only two stations located within the project area (both upstream of the Turners Falls dam) and only collected five to six samples from late April to early October. The Connecticut River Watershed Council's volunteer monitoring program only had one sample site within the project area (at Barton's Cove in the Turners Falls impoundment) and while those data are more recent, only three samples were collected in 2007 and only six samples in 2008 (over the course of three to four months each year). The U.S. Geological Survey's long-term water quality monitoring station located downstream of the Cabot Station tailrace only collects information roughly once per month (and no dissolved oxygen data are provided).

No directed, site-specific surveys have been conducted to determine whether waters within the Project area meet state standards. This information gap needs to be filled so that resource agencies can evaluate properly the potential impact of project operations on water quality.

Nexus to Project Operations and Effects

The project creates a 20-mile-long impoundment where there would naturally be a free-flowing river. It currently operates in a peaking mode, with allowable river fluctuations of up to 9 feet, with proposals to continue as such. Portions of the impoundment are nearly 100 feet-deep. There is a 2.7 mile-long reach of river bypassed by the Turners Falls power canal with only a nominal seasonal release required (equal to 0.05 cfs). The below-project flow requirement is equal to 0.20 cfm (1,433 cfs). Water quality is directly affected by the operating mode of a hydropower project. Impoundments can stratify, resulting in a near-hypoxic hypolimnion. If the project intake draws off of these deep

waters then it could cause low dissolved oxygen levels downstream from the project discharge.

The Landowners and Concerned Citizens for License Compliance requests that the applicant conduct a water quality survey of the impoundment, bypass reach and tailrace reach in order to determine whether state water quality standards are being met under all currently-licensed operating conditions (i.e., during periods of generation and non-generation). Results of the survey would be used, in conjunction with other studies requested herein, to determine an appropriate below-Project flow prescription, bypass reach flow(s), and to recommend an appropriate water level management protocol for the impoundment (e.g., limiting impoundment fluctuations to protect water quality). Operation of upstream hydroelectric projects as well as the Turners Falls Project and Northfield Mountain Project may impact water quality through the use of water for hydropower generation.

Methodology Consistent with Accepted Practice

Turners Falls: Water quality samples should be collected from a minimum of six locations: upstream of the impoundment, at a deep location within the impoundment, in the forebay near the intake, in the bypass reach, in the canal near Cabot Station and downstream of the confluence of the Cabot Station discharge and the bypass reach but upstream of the confluence with the Deerfield River. In order to ensure that data are collected under “worst case” conditions (low flow, high temperature, antecedent of any significant rainfall event), we recommend deploying continuous data loggers at all six locations, with biweekly vertical profiles taken at the deep impoundment location from June 1 through September 30. Results should include date, time of sampling, sunrise time, GPS location, generation status (estimated flow through canal and bypass reach), precipitation data, water temperature, DO concentration and percent saturation.

In addition, impoundment sediment adjacent to the Turners Falls dam should be analyzed for metals and polychlorinated biphenyls.

A proposed water quality sampling plan should be submitted to USFWS and MADEP for approval. A section on quality assurance and quality control must be included.

If river flow and temperature conditions are representative of an “average” or “low” water year, then one year of data collection should be sufficient to perform the study. If conditions are not representative (i.e., a “wet” or cool year) then a second year of data collection may be necessary.

Northfield Mountain: The water quality study will include two components: a) continuous dissolved oxygen and temperature monitoring at specific locations in the Northfield Mountain Project area and b) monthly *in-situ* dissolved oxygen, temperature profiles, total suspended solids and turbidity within the Northfield Mountain Upper Reservoir. It is anticipated that the study will be conducted from approximately June 1 through September 30.

Level of Effort and Cost

Cost would depend on the specific methodology chosen. If continuous data loggers are installed at all six locations and biweekly vertical profiles taken at the deep impoundment location from June 1 through September 30 then the estimated cost of the water quality study is approximately \$55,000, including at least one full year of data collection. It is expected to take two technicians approximately one day to deploy the loggers, eight days to collect the vertical profiles, one day to remove the loggers, one day to download the data, and five days to write the report.

In the PAD, the applicant proposes to assess the effects of the Turners Falls and NFMPS project operations on dissolved oxygen and temperature by continuously monitoring DO and temperature at locations within the project areas and gathering vertical profiles within the TF impoundment and NFMPS upper reservoir.

Study Request 6a – Quantify the Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation Including Invasive Species and their Associated Habitats in the Turners Falls Dam Project Impoundment

Conduct a study to quantify the impacts of river level fluctuations due to project operations on riparian, wetland, Emergent Aquatic Vegetation (EAV), Submerged Aquatic Vegetation (SAV), littoral zone and shallow water aquatic habitats in the Turners Falls Dam impoundment.

Goals and Objectives

The goal of this study is to obtain baseline information on riparian, wetland, emergent and submerged aquatic vegetation, and associated shallow water aquatic habitats (subject to operational inundation and exposure to near exposure) known to occur in the project area. Information would be used to determine whether riparian, wetland, EAV and SAV, littoral, and shallow water (e.g., mid river bars and shoals) habitats are impacted by current water level fluctuations permitted under the Turners Falls and Northfield projects' licenses and whether these vegetation types and shallow water habitats can be protected and restored by modifications to project operations or other mitigation measures. This analysis needs to take into account existing and potential future limits on pond level fluctuations intended to limit recreation impacts, and the interactions of any changes in pond level fluctuation range or frequency and discharge changes under a new licenses of the Turners Falls and upstream projects. This information is needed to determine whether the projects' operation affects plants, habitat, and wildlife in the project area, whether aquatic vegetation and its habitats can be enhanced by modifications to project operations or other mitigative measures, and whether there is any unique or important shoreline or aquatic habitats that should be protected.

The specific objectives of the field study, at a minimum, include:

- Quantitatively describe and map wetland types within 200 feet of the shoreline, and describe associated wildlife;
- Delineate, quantitatively describe, and map all wetland types including invasive species and wildlife observed (e.g., bald eagle nesting, water fowl nesting) within 200 feet of the shoreline, and the extent of this habitat if it extends beyond 200 feet; and
- Quantitatively describe (e.g., substrate composition, vegetation type and abundance) and map shallow water aquatic habitat types subject to project operation inundation and exposure, noting and describing additional areas where water depths at lowest operational range are wetted to a depth less than one foot (flats, near shore areas, gravel bars, with very slight bathymetric change);

A second year of study may be required should river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period.

The field study should produce a habitat inventory report that includes:

- The results of the field study in the form of maps and descriptions;
- An assessment of project effects on wetland, riparian, littoral zone vegetation and shallow water habitats, invasive plant species, and wildlife habitat at the project; and
- Recommendations for any necessary plant, habitat type, or wildlife, protection and/or invasive species control measures.

Relevant Resource Management Goals and Public Interest Considerations

Protect and restore native riparian, wetland, EAV, SAV, littoral and shallow water habitat (i.e., spawning and or nursery areas for aquatic organisms) in the Turners Falls impoundment.

Public Interest Considerations if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information and Need for Additional Information

Existing information in the PAD does not quantify EAV and SAV in this area, or other shallow aquatic habitat types and physical features (e.g., depths, substrates, wood structure) that are the environment for aquatic biota in the project area. The PAD does provide some limited monitoring data for 2012 (2 locations) on water surface elevations that show daily fluctuations, in the upper third of this impoundment, that varied over 4 feet on a daily cycling frequency, with fluctuations generally in the 2 foot range in low flow months for the data provided in the PAD. The current license does permit a greater

pool elevation operational fluctuation, up to a 9 foot change in elevation, based on the Turners Falls Dam water elevation. In the PAD it is noted these operational fluctuations under most circumstances at the Turners Falls Dam are within 3.5 feet.

In the PAD it is noted that FirstLight would like to expand its NMPS upper reservoir capacity (by up to 24%). How this may affect project operations and the habitats noted in this request is unknown. It is also noted that water is typically pumped to the upper reservoir in evening and generation back to the river occurs once to twice daily, in daytime hours, based upon power needs and power value. Under current license conditions, provided set thresholds for minimum flow and Turners Dam current license elevations are met, the NMPS may operate with no restriction in timing, frequency, or magnitude for pumping or generation. No data were provided on the operation of the NMPS plant over time relative to data on pumping and generation on an hourly basis, averaged values were provided over monthly periods. It is unclear what the actual timing, frequency and magnitude of these NMPS operations are over the course of a year and how that relates to: aquatic plant species establishment, growth, survival, littoral zone or other shallow water habitat fish spawning periods and their effects on these fishes (reproduction success and subsequent recruitment, e.g., bass and fall fish nests) in available and utilized habitat, and how the quantity and quality of these shallow water habitats are effected by project operational manipulation/alteration, as currently permitted or proposed.

The PAD provides lists of plant and wildlife species whose native ranges overlap with the project area, but it does not provide any baseline information on known occurrences of these species in the wetlands, riparian, littoral and shallow water habitats, within or adjacent to, the project area. Plant and wildlife occurring in these habitats may benefit from protection, mitigation, and enhancement (PMEs) measures, given the potential effects of continuing the current semiautomatic peaking operating regime. In addition, a large scale sediment discharge from NMPS resulted in regulatory actions by FERC, the EPA and MADEP in 2010. Continuing and as yet unresolved management plan measures relative to sediment and NMPS project operations, are further concerns for shallow water, littoral zone, and wetland habitats.

The Atlantic States Marine Fisheries Commission, Atlantic Coast Diadromous Fish Habitat: A Review of utilization, threats, recommendations for conservation, and research needs (ASMFC 2009)², contains a review of habitat information for these species. Recommendations in this report include: Maintain water quality and suitable habitat for all life stages of diadromous species in all rivers with populations of diadromous species.

Nexus to Project Operations and Effects

Water level fluctuations due to project operations could affect EAV and SAV habitat as well as the quantity and quality littoral and shallow water habitat. These operational

² Atlantic States Marine Fisheries Commission. 2009. Atlantic coast diadromous fish habitat: A review of utilization, threats, recommendations, for conservation, and research needs. Habitat Management Series #9. Washington, D.C.

water level fluctuation effects are expected to impact fish species use of these habitats and may affect spawning fishes reproductive success and subsequent population recruitment including but not limited to American shad, blueback herring, sea lamprey, fall fish, and bluegill, which spawn in mid to late spring through early summer in areas subject to daily or more frequent water level fluctuations.

The current operating mode, as well as the unknowns with proposed upper reservoir expansion, may affect wetland riparian, littoral and other shallow water habitats and promote the introduction and expansion of invasive plant species through fluctuating water levels. A study that explains the relationship between the proposed mode of operation and the type and quantity of wetland, riparian, littoral, shallow water habitats, and invasive species affected would help inform a decision on the need for protection and/or control of these resources in the license.

Methodology Consistent with Accepted Practice

The PAD currently contains maps portraying general wetland types from the Cabot Station tailrace upstream to the Vernon Dam. In addition, we understand that recent bathymetry exists for the Turners Falls impoundment (Field, 2007). The proposed study should utilize this existing information in conjunction with field surveys designed to describe the characteristics of each mapped wetland, riparian, littoral and shallow water habitat including plant species composition, relative abundance/density, habitat quality, and land use. These surveys should be conducted to describe these habitats at the lowest water level operational range permitted on a daily operation schedule, under low flow conditions. Information collected should include:

- Plant species composition, and their relative abundance/density and condition/structure (e.g., seedlings);
- Structured data, including estimates of average heights and aerial cover of each vegetation layer (specifically denoting invasive species);
- Aquatic habitat substrate composition, quantity (i.e., percent types and area), wood structure (relative abundance measure applied by area), water depths (inundated, exposed, and water less than one foot);
- Predominate land use(s) associated with each cover type;
- Wildlife sightings should be noted;
- Field verified wetland, riparian, and littoral and shallow water habitats and invasive species occurrences, should be geo-referenced as polygons and overlain on orthophoto at a suitable scale.

Level of Effort and Cost

In the PAD, First Light identified impacts of the project operations on wetlands, riparian and littoral zone habitat as a potential issue to be addressed in relicensing, and proposed wetland vegetation mapping. However, additional analysis as described above is needed to understand the impacts of the project on these resources and habitats.

A wetlands, riparian, littoral/shallow water, invasive species inventory, of the scope envisioned, would likely require 6-8 months to complete and cost \$40,000 to \$50,000.

Study Request 7a - Model flows in the Northfield Mountain Pumped Storage Project discharge tailrace and Connecticut River 1 kilometer upstream and downstream of the discharge using two-dimensional Computational Fluid Dynamics (CFD) model techniques.

Goals and Objectives

The goal of this study is to determine the potential impacts (both project-specific and cumulative) of the Northfield Mountain Pump Storage Project operations (pumping and generating) on the zone of passage for migratory fish near the Northfield Mountain turbine discharge/pump intake, on natural flow regimes in the area of the Connecticut River immediately upstream and downstream of the project, on the potential for entrainment during pumping operations, on the potential for creating flow reversals in Connecticut River during pumping cycles that may confuse migratory fish attempting to pass the project, and on bank erosion on both sides of the river in the vicinity of the tailrace.

Specific objectives of the study include:

- Develop a 2-dimensional CFD modeling capability for the area of the Northfield Mountain discharge and tailrace, along with the full width of the Connecticut River 1km upstream and 1 km downstream of the discharge.
- Model flow characteristics upstream and downstream of the project under existing project operations (pumping and generating) and at several representative river flow levels, as well as proposed operations such as those proposed in section 3.4.4 of the PAD, and any other modifications under consideration, to assess potential impacts to fish and wildlife resources, recreational use, agricultural resources, and historical resources.
- Assess velocities at and in proximity to the Northfield Mountain intake/discharge structure, when pumping or generating and their potential to interfere with fish migration.
- Assess the potential for velocity barriers in the mainstem river resulting from pumping and generation flows at the project, alone or in combination with generation flows from the upstream Vernon Project.
- Assess potential for Northfield Mountain project operations to create undesirable attraction flows to the intake/discharge that may result in entrainment or delay of migratory fish.
- Assess the potential of a mainstem instream local flow reversal associated with pumping operations to impact migrating fish. The Connecticut River in the area of the Northfield Mountain tailrace has been said to flow upstream potentially confusing migratory fish keying in to flow as a directional aid to upstream or

downstream migration, causing delay and additional "fish" energy expense and possible entrainment.

- Model and then evaluate flow characteristics under alternative project operations with potential measures to avoid, minimize, or mitigate impacts to fish and wildlife resources.
- Assess the potential for unnatural flows and eddies in the main-stem associated with pumping or generation at the Northfield Mountain Project to impact bank erosion and recreational use.

Resource Management Goals

The Landowners and Concerned Citizens for License Compliance supports the U.S. Fish and Wildlife Service's goals. The mission of the U.S. Fish and Wildlife Service (Service) is to work with others to protect, conserve and enhance fish, wildlife, plants and their habitats for the continuing benefit of the American public. Service trust resources include wetlands, endangered species, and migratory species, all of which have been documented to occur in the project area. The Service is also working with a number of federal, state, local, non-governmental organizations, and the public to restore and enhance trust resources in the Connecticut River Basin through comprehensive management plans and cooperative agreements. Instream flow is an important riverine habitat characteristic that can have a great impact on aquatic habitat for fish, wildlife, and plants. Flow is an important directional guidance cue for instream navigation and attraction to fishway entrances for migratory fish.

Public Interest Consideration if Requester is not a Resource Agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information

No project specific information exists that will allow for a comprehensive assessment of existing project operations (pumping and generating flows) on Connecticut River flows and on fish and aquatic organisms in the project area upstream and downstream of the project in the Connecticut River. Preliminary results from an ongoing study of radio-tagged American shad by the USFWS and USGS Conte lab indicate that shad are exposed to the intakes and some individuals spend substantial amounts of time in the vicinity of the intakes. The PAD does not contain any information or tool that will allow for predictions of impacts of alternative project operations, or potential mitigation measures to protect or enhance aquatic fish and wildlife resources.

As part of Field (2007; see appendix 4), a “Connecticut River Hydraulic Analysis – Vernon Dam to Turners Falls Dam” was completed by Woodlot Alternatives in July 2007. For this analysis, a 2-dimensional flow model was developed for the entire Turners Falls impoundment. This study was geared towards looking at shear stresses from high-flow events, and did not focus in detail around the tailrace or examine how pumping and generation may affect flows in the vicinity of the tailrace under a variety of flows.

As a result of the hydraulic analysis, Field (2007) on page 20 states that “While erosion does occur where high flow velocities and shear stresses approach near the bank, significant amounts of erosion also occur where flow velocities near the bank are low.” No specific examination was done in the report on the ± 1 km area near the tailrace and existing erosion sites. Banks immediately upstream and downstream and across river have all required bank stabilization projects over the last 15 years, in some cases needing several repairs.

Nexus to Project Operations and Effects

Existing project operations have a direct impact on instream flow and aquatic habitat in the pump/discharge area of the Connecticut River. The PAD in section 3.2.2 says that the velocity at the trash racks when operating at full capacity is 20,000 cfs and maximum pumping conditions are 15,200 cfs. Annual flow duration curves shown for below the Vernon Dam submitted in the PAD section 4.3.1.2 (for years 1944-1973; recent and near project flows are not available; see p. 459) indicate that river flows are $\leq 20,000$ cfs more than 85% of the time. Flows released from the project must therefore influence flow patterns and velocities in the Connecticut River, particularly at flows below some unknown threshold level.

Recreational users of the Connecticut River in the Turners Falls impoundment have anecdotally described flow reversals in the mainstem river. Discharges from the project could potentially be larger than river flows or at least act like a major tributary to the Connecticut River. Project flows may influence the availability and extent of upstream and downstream migration zones, or may confuse fish and delay migration. Project flows may also impact stream banks in ways that natural river flow (or flows affected by upstream hydropower facilities) does not, and may also impact recreational use of the river.

Proposed Methodology

CFD modeling is consistent with generally accepted practice, and has been used to assess proposed modifications to the Holyoke Dam fish passage facilities, upstream of the intakes and downstream of the dam, as well as at hydroelectric projects on the Susquehanna River to assess existing and proposed project operations, and develop mitigation measures for fish and wildlife resources.

Level of Effort/Cost, and Why Alternative Studies will not suffice

This study will require a detailed elevation map of the study area upstream and downstream of the Northfield Mountain project. Information already exists in historic construction files for the project, the hydraulic analysis included in Appendix 4 of Field (2007), and possibly in conjunction with work done after the 2010 maintenance procedures that resulted a portion of the river being dredged after a large sediment dump) that are in the possession of the applicant. Additional elevation data will likely need to be collected in the field using standard survey techniques. Elevation data will then need to be entered into a CFD modeling program. The CFD computer program will need to simulate existing project operations that include all potential variations of pumping and generating, and static operation. No project specific instream flow analysis tool has been developed for the Northfield Mountain project that will allow for assessment of existing operations and alternative operational impacts on instream flow and aquatic habitat for fish and wildlife resources. The computer model, once built, can be used to simulate flow conditions in the vicinity of the project during migratory fish passage and can be used together with behavior studies (i.e., telemetry studies and entrainment studies requested herein) to assess the impacts of varying project operations or potential mitigation operations and measures on fish migration and aquatic habitat. We know of no other tool that will provide for these types of assessments. Cost is expected to be moderate to high.

Study Request 8a. Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations

Develop a river flow model(s) that are designed to evaluate the hydrologic changes to the river caused by the physical presence and operation of the Turners Falls Hydroelectric Project and the interrelationships between the operation of all five hydroelectric projects up for relicensing (i.e., P-1889 Turners Falls Hydroelectric Project, P-2485 Northfield Mountain Pumped Storage, P-1904 Vernon Hydroelectric Project, P-1855 Bellows Hydroelectric Project, P-1892 Wilder Hydroelectric Project) and river inflows. The flow studies should assess the following topics:

1. Conduct quantitative hydrologic modeling of the hydrologic influences and interactions that exist between the water surface elevations of the Turners Falls Project impoundment and discharges from the Turners Falls Dam and generating facilities and the upstream and downstream hydroelectric projects. Data inputs to and outputs from the model(s) should include:
 - a. Withdrawals from the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project, FERC No. 2485,
 - b. Discharges to the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project,
 - c. Discharges into the Turners Falls impoundment from the Vernon Project, FERC No. 1904 and other sources.
 - d. Existing and potential discharges from the Turners Falls Project generating facilities and spill flows.
 - e. Existing and potential water level fluctuation restrictions (maximum and minimum pond levels) of the Turners Falls impoundment and downstream flows from the project
 - f. Existing and potential required minimum flows and/or other operation requirements at each of the four upstream projects.
 - g. Minimum discharge flows ranging between 2,500 and 6,300 cfs in the bypass reach from April 15th through June 22nd to support spawning, rearing, and outmigration of shortnose sturgeon at Rock Dam.
2. Document how the existing and potential outflow characteristics from the four upstream projects affect the operation of the Turners Falls Project including downstream flow releases and Turners Falls impoundment levels.
3. Assess how the operation of the existing Turners Falls Project and upstream projects affect Holyoke Project (P-2004) operations including:
 - a. How Turners Falls Project flow fluctuations affect Holyoke impoundment water levels, with emphasis on the influence on the water levels on listed Puritan tiger beetle habitat at Rainbow Beach in Northampton, MA. and assess what changes would be needed in Turners Falls operations to stabilize water levels at Rainbow Beach.

- b. How Turners Falls Project operations affect Holyoke Project discharges and what changes in Turners Falls operations would be needed to reduce fluctuations in the discharges from the Holyoke Project.
4. To the extent predictable and practical, incorporate the potential effects of climate change on project operations over the course of the license.

Goals and Objectives

Determine the extent of alteration of river hydrology caused by operation of the project and the interactions between upstream project operations, Turners Falls operations and downstream operations at the Holyoke Project. The models will provide necessary information on what changes can be made to each of the five project's flow releases and/or water levels restrictions, and how those changes affect downstream resources.

Specifically, for the Turners Falls Project continuous minimum discharge flows in the Turners Falls bypass reach need to be no less than 2,500 cfs during shortnose sturgeon spawning, rearing, and outmigration (April 15th – June 22nd). Incorporating these parameters into the model will inform what changes, if any, need to be made to operations of upstream projects to accommodate such flows.

As other specific modifications of the operations of each of the projects are identified based on results of other requested studies, these desired conditions will need to be input into the models to assess how each change affects that project and other project operations and the implications of those changes on other resources and/or the ability to achieve desired operational changes at other projects.

Resource Management Goals

The Landowners and Concerned Citizens for License Compliance support the goals of the U.S. Fish and Wildlife Service (Service). The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Assist FERC to ensure that the continued operation of the facility is not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources, the Service's goals are:

1. Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
2. Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.

3. Minimize current and potential negative project operation effects on water quality and aquatic habitat.
4. Ensure that project operations are not likely to jeopardize the continued existence of shortnose sturgeon.
5. Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing within the Montague spawning area (i.e. Rock Dam and Cabot Station spawning sites and associated early life stage rearing areas).

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest considerations if requester in not a resource agency

The Landowners and Concerned Citizens for License Compliance (LCCLC) consists primarily of Gill and Northfield farm and conservation landowners who organized after seeing our riverbanks continue to wash down the Connecticut River in the Turners Falls Pool. Current and previous landowners have consistently advocated for more and better work to stabilize and repair areas of bank erosion with numerous filings to FERC, including professional studies commissioned by LCCLC, all of which have been made a part of the licensing proceeding.

The LCCLC has active members on the Franklin Regional Council of Governments' (FRCOG) Ad Hoc committee, the Connecticut River Streambank Erosion Committee (CRSEC). The CRSEC was convened in 1994 to bring together the Northfield Mountain Pumped Storage Project operator, state and municipal entities, landowners, and NGO's to carry out bioengineering projects to stabilize and repair areas of bank erosion. We are currently working with the FirstLight and the CRSEC to develop a suitable Quality Assurance Project Plan (QAPP) and appropriate methodology for the 2013 FRR.

The LCCLC looks forward to continuing our active engagement in the relicensing of the Turners Falls Dam and Northfield Mountain Pumped Storage Projects

Existing Information

Available information in the PAD does not indicate how project operations have altered downstream hydrology, which may affect resident and migratory fish, macroinvertebrates, rare, threatened, and endangered species, aquatic plants and other biota and natural processes in the Connecticut River from below the Vernon Dam downstream to the Holyoke Dam.

Information in the PAD also does not reflect data analyzed in Kynard et al. 2012, which identifies minimum discharge thresholds for shortnose sturgeon spawning and rearing at

the Rock Dam spawning site. Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period (April 27–May 22nd) (Kynard et al. 2012, chapter 3). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 ELS captured, spawning period was 17 days) even though no spawning was detected at Rock Dam (Kynard et al. 2012, chapter 3). Discharges in 1995 at Rock Dam had dropped below 2,500 cfs by March 26th (Kynard et al. 2012, chapter 3), showing that even though 1995 saw the largest number of pre-spawning adults, none spawned at Rock Dam. This may indicate the need to have adequate flow well in advanced of spawning. Discharge reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning cite and not return even if flow increased to acceptable levels later during the spawning period. Researchers observed that substrate did not change during fluctuating flows and thus cessation of spawning is likely due to velocities falling below the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kynard et al. 2012, chapter 3). These data represent the best available scientific information and indicates that the current minimum flow thresholds at the project are not adequate for the protection of endangered shortnose sturgeon. All modeling efforts described above must incorporate the identified minimum flow and temporal parameters.

Nexus to Project Operations and Effects

The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (400 cfs from 5/1 through 7/15, then 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flow below the projects of 1,433 cfs. The project operates as a daily peaking project, often with large, rapid, daily flow fluctuations between the minimum and project capacity (15,928 cfs) and fluctuations in headpond elevation (175' to 186' MSL). These changes affect biotic habitat and biota upstream and downstream of the project. Project operations and potential changes to operations to mitigate impacts are influenced by inflows and operations of upstream peaking projects and the Northfield Mountain Pumped Storage Project operations and potential changes in operations of each project could affect the ability to achieve desired operational changes at other projects. Results of river flow analyses will be used to develop flow-related license requirements and/or other mitigation measures.

Methodology Consistent with Accepted Practice

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess implications of project operations on the river environment.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Level of effort and cost of model development are expected to be moderate but to be valuable in developing license conditions, the model(s) will need to be run under various scenarios throughout the relicensing process to assess the implications of changes to the operations of each project on other projects and other resources. Therefore, ongoing consultation and re-running of the model(s) are likely to be needed

throughout the relicensing process. The modeling exercise will also require coordination and cooperation between First Light and the upstream licensee to assure that the model inputs and outputs can be accurately related.

We would anticipate that the expected level of effort and anticipated costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., Conowingo, FERC No. 405).

Mary Jo Maffei, Amherst, MA.
Re-licensing Northfield Mountain P-2485-063

Northfield Mt. is a treasure. There are beautiful hiking, snowshoeing and cross-country trails and the grooming of the ski trails is excellent. As a parent and manager of the Amherst High School Nordic ski, the mountain provides a place for the kids to ski and train. However, more access needs to be provided. Skiers at Notchview run by the Trustees of the Reservation in Windsor, MA can ski any time, skiers should be able to ski any time at Northfield Mt. The mountain needs lights for night skiing and the ability to make snow. Currently, the mountain is closed on Monday and Tuesdays and closes at 4:30 PM. Our team skis after school, arrives at the Northfield around 3 PM and can only ski for an hour and half although there is adequate light to ski for longer. Often the mountain is closed when there is snow on upper trails, but not lower trails. Also, Northfield should be available to host high school Nordic ski meets. Currently they are unwilling to do this.

Northfield Mt. would be an ideal place to make snow. There is no trouble accessing water and the lower trails are in the shade and would hold snow for a long period of time. A five kilometer loop of man-made snow would be ideal. This would allow for skiing throughout the season and would make Northfield Mt. a truly valuable resource for outdoor recreation in Massachusetts. Northfield Mountain should provide:

- 1) Expanded ski hours - 24/7
- 2) Snow making for a loop - ideally 5 kilometers
- 3) Lights for snow making loop for night skiing.

Thanks you and please feel free to contact me for more information.

RE: Northfield Mountain Pumped Storage Project, FERC Project No.2485

Dear Secretary Bose:

My family farms roughly 275 acres in the Pioneer Valley of Western Massachusetts. For more than 25 years we have drawn water for irrigation purposes from the above referenced project area. Over the years we have made considerable efforts to comply with every governmental requirement, and many additional voluntary ones. We possess all applicable local, state, and federal permissions for our withdrawals. We have however been involved in a protracted legal struggle with First Light Power Resources and their predecessor Northeast Utilities regarding the need for us to receive permission from them for these same withdrawals. As part of the relicensing effort we request that First Light's license be amended to include language clarifying that First Light does not have authority over withdrawals for irrigation purposes.

My parents purchased the land on which the farm now operates in 1986 and have worked much of their adult life to pay off the mortgage, raise a family and create not only a world class farm, but one that is sustainable both environmentally and financially. While my parents are still the primary owners of the farm, we are currently undergoing a transition both of ownership and management to my brother and I. We grew up on this farm, we were ages 8 and 10 when it was bought, and have spent most of our lives on it. After college and brief periods off the farm, we have both returned to it, built homes and families, and hope to continue what my parents have started.

The farm has grown a variety of crops over its 25 year history. Sod has been a major crop for the entire period, but we have also grown nursery stock, and raised fish. In the last 5 years we have made a gradual transition and have begun to produce food crops, returning hops and many small grains to the valley, something that hasn't been done on the scale we have achieved here in Western Massachusetts for over 100 years. It's been a struggle, and it hasn't been inexpensive. We have however always found a way not just to get by, but to grow incredibly high quality crops in an environmentally sustainable manner and to market them at a price that sustains our family.

One of the centerpieces of our farm, one of the key factors that attracted my parents to it, was its access to water. With over a mile and a half of frontage on the Connecticut River (with existing access)

and the finest soils in the world, it was impossible to not make the leap from the small farm they operated in Rhode Island and move north those 25 years ago.

That river supplies our farm with a lifeline for the crops we grow – water. Without a reliable access to water we cannot make the investments we need to assure a viable farm in the future. Each crop we grow has required this water and its proximity and ease of withdrawal is one of the farms greatest assets.

Over the years we have taken great efforts to comply with every local, state and federal rule and voluntary program we have encountered. We have all the necessary permits and licenses to pump from the river (at a cost of over \$50,000 despite not needing to move a shovel full of dirt or cut a single branch within 100 feet of the river). Several years ago however we were approached by then “Northeast Utilities” (NU), a power generation company that operated the Northfield Mountain Pump Storage Project and were told we could no longer pump from the area of the river used as the lower reservoir of their pump storage facility. The license they held from the Federal Energy Regulatory Commission (FERC) gave rights to draw from this portion of the river to NU, and allowed them to grant permission directly to those withdrawing from the area. Further it required that NU monitor and take all lawful measures to assure that such withdrawals where in compliance with the law. We would need to obtain permission from them or they would sue us in federal court.

We strongly disagreed with their legal interpretation of the license and traded letters for many years. Our position was simple – while FERC may have granted extensive powers to NU, Congress’s grant of powers to FERC was limited and specifically did not grant FERC the power to affect state laws governing the use or distribution of water used in irrigation [see US Code Title 16, Chapter 12, Subchapter 821 – States laws and water rights unaffected]. Massachusetts has an array of laws, permitting mechanisms, water resource management plans, and constitutional provisions guaranteeing access to water for agriculture, all of which would clearly be affected by an interpretation of the project license in such a way that required permission from the utility for such withdrawals. NU eventually just stopped responding to our replies and the issue seemed dormant.

Northeast Utilities sold the Northfield Mountain Project to First Light Power Resources several years ago, and after an initial period of quiet, the letters began again, likely in preparation for First Light’s upcoming license renewal. We again tried the same tactic, with the help of an attorney showing the simple argument that while FERC may have given First Light what First Light perceives as clear instructions in its license to control all access to the river, the matter was not so simple and the license must be taken in context to the power that FERC has. This was unsuccessful, and in a simple calculation of the effect on our farm’s viability that tens of thousands of dollars for a protracted legal battle in federal court would have, we decided to acquiesce and obtain from a 100% private company the right to use a public water body that the farm had always used. That permission may be revoked with or without cause at any time by First Light with no appeal, and leaves our farm at the mercy of a private corporation.

On October 30th, 2012 First Light Power Resources submitted a combined pre-application document for relicensing of the Northfield Mountain Pumped Storage Project, FERC Project No.2485; and Turners Falls Hydroelectric Project, FERC project No.1889. It is the language of the license that has First Light convinced that they not only may, but in fact must, police and grant or deny permission for all withdrawals from the portion of the river that we draw from.

For project licensing by FERC, their rules specifically state that before approval the project "shall be such as in the judgment of the Commission will be best adapted . . . for other beneficial public uses, including irrigation . . ." [US Code Title 16, Chapter 12, subchapter 803, (a) (1) Modification of plans; factors considered to secure adaptability of project; recommendations for proposed terms and conditions].

We are seeking assistance to add language to First Light's license that clarifies that use of water within the lower reservoir for irrigation is not subject to oversight in any way by First Light. We are not seeking any exemptions or special accommodation for irrigation use of the river from the state or federal government, and possess all required permits and approvals from them for this activity. We are asking for your assistance to remove First Light as an unnecessary intermediary in an area that Congress never intended they be. Addition of such language would help make the project better adapted for irrigation use and provide the certainty necessary for our farm. The oversight of the local, state, and federal government, while challenging at times, is subject to basic elements of good governance (open meeting laws, public records request, both administrative and judicial appeals, etc . . .). We feel that these protections while not being a 100% assurance of our access to water provide greater certainty and reliability and will thus allow us to continue to invest in long term projects on our farm.

Sincerely,

Nathan L'Etoile

Federal Energy Regulatory Commission
Attn: Ken Hogan

RE: Northfield Mountain Pumped Storage Project
FERC No. 2485-063

The Western Massachusetts Climbers' Coalition respectfully submits the following scoping comments with regards to the Northfield Mountain Pumped Storage Project. The Western Massachusetts Climbers' Coalition (WMCC) is a 501(c)(3) non-profit organization representing over 500 members and whose primary mission is to advocate for the protection and preservation of the unique and valuable outdoor rock climbing resources in western Massachusetts. As such, we request that three additional issues be considered in the scoping document for the Project.

First, we request that rock climbing be considered as a valid and important outdoor recreational opportunity within the Project boundaries. The Northfield Mountain Pumped Storage Project property contains two of the most significant rock climbing resources in southern New England, Rosc Ledge and Farley Ledge (aka Rattlesnake Mountain). These two cliffs have been attracting New England based climbers, adventure programs and school groups since the 1940's. These sites represent significant historical resources for the sport. As the popularity and interest in rock climbing continues to grow, high quality and accessible climbing resources close to major population centers become increasingly important.

Second, we request that a change in the collection and evaluation of recreational survey data. We feel that methodologies should be expanded to include online surveys and/or surveys distributed through, or with the help of, organizations such as the WMCC who have a better understanding of the ways in which their members and supporters use and access the available resources. Particular site conditions, weather, timing and access points are generally different for each user group and without an understanding of those specific environments, a large percentage of recreational is potentially ignored.

Lastly, we request that additional protection efforts be considered for important and valuable resources currently within Project boundaries that are otherwise unprotected. The environmental resources that comprise Farley Ledge and its immediate surrounding have been identified by the Massachusetts Natural Heritage and Endangered Species Program as Core Habitat area containing a Priority Natural Community and Species of Special Concern. These resources include valuable animal habitats such as that of the peregrine falcon. This species has - with the help of the WMCC - reestablished itself on the cliffs, making Farley the first natural nesting habitat in Massachusetts for

the species since the 1970's. Additionally, the vegetative community found among the cliffs has been identified as an Acidic Rock Cliff Community and an Acidic Talus Forest/Woodland. This unique combination of plants and flora is one of only six identified in the state. We are requesting that FERC and First Light consider additional protection efforts and conservation restrictions, with the help of the WMCC and other agencies, to ensure the protection of these valuable natural resources in perpetuity.

Sincerely,

Jeffrey Squire
President
Western Massachusetts Climbers' Coalition

Re: application for re-licensing of the Northfield Mountain Pumped Storage Project (P-2485-063), the Vernon Project (P-1904-073) and the Turners Falls Project (P-1889-081)

Submitted by Joan Deely on behalf of the Northfield Conservation Commission

The Northfield Conservation Commission serves the Town of Northfield, MA. Ours is the only community in the entire watershed that is bisected by the Connecticut River, which flows past prime farmland on both sides.

Consequently, the health and function of the river, and its impact on our lands, are of great importance to us.

The public-access boat ramp in Northfield is often inaccessible to boats due to extreme fluctuations in water levels on the river. This is a critical point of entry for emergency responders from the Northfield Dive Team, which plays an important role in the safety of recreational boaters and citizens alike.

Our daily lives are impacted by the three project referenced above.

We are keenly interested in identifying and implementing solutions that protect prime farmland, structures, and other natural resources, not only in Northfield, but in all the communities along the Turners Falls Pool.

Since the new licenses for the three projects will be valid for 30 to 50 years, we all have a "once in a lifetime" opportunity to participate in the process to identify, evaluate and mitigate the environmental impacts of these projects.

It is vital for the residents and municipalities of Franklin County to be actively represented and engaged in the relicensing process to ensure that the health and vitality of the river is sustained; to protect the region's treasured prime farmland, riparian and aquatic habitat for rare and endangered species; to ensure the safety of those using the river for recreation; and to make sure that recreational areas and facilities are maintained. We hope that FERC will hold the owner of the hydroelectric projects to high standards and expectations.

We have been and continue to be concerned with the frequent and significant water level fluctuations associated with the operation of the Northfield Mountain Pumped Storage and Turners Falls projects, which result in streambank erosion and impacts to water quality, threatened and endangered species, fisheries, wetlands, and riparian and littoral habitat. In particular, we believe that the Northfield Mountain Pumped Storage project and its operational use of the Connecticut River have been a long-term “experiment” that has resulted in significant adverse environmental impacts.

Our regional economy benefits from the number and variety of recreational resources associated with the projects. We appreciate the applicant’s efforts to maintain and enhance the projects’ recreational opportunities over the years. We encourage the applicant to continue their stewardship and to proactively engage with local towns and regional groups to expand and enhance the recreational opportunities, which in turn will help to strengthen the economy of Franklin County. Tourism is important to the economy of Franklin County, which is one of the poorest counties in the state.

We now have an opportunity to seriously consider the benefits of taking the river “off-line” and creating a closed-loop lower reservoir that would address most of the environmental impacts and specific resource concerns raised by Federal and state agencies and stakeholders.

We believe that the magnitude of river alteration caused by these projects, along with the complexity of issues involved and controversies about the best approaches to maintain power generation while not decimating aquatic communities and other natural resources, fully warrants an Environmental Impact Statement (EIS) under NEPA. We endorse FERC’s approach to developing a single EIS for the five Connecticut River hydroelectric facilities to evaluate their individual and cumulative impacts on the river ecosystem. Now is the best opportunity in the near and long term to look at all these facilities holistically.

We have expressed our concerns about the methodology, findings and conclusions of the 2008 Full River Reconnaissance to FirstLight and FERC. We want to reiterate our concerns here, and state that accurate data and a reproducible methodology are essential for documenting the type and stage of erosion in the pool, and for evaluating whether the pace of erosion control work is keeping up with the rate of erosion. We request that the relicensing record reflect our continuing objections to the findings of the 2008 FRR, and specifically, our objections to including statements in the PAD that reference the 2008 FRR, and all of the text on page 4-12 of the section *4.2.4.2 Shoreline and Streambank Characterization*.

Concerns of the Northfield Conservation Commission include the following:

- The original purpose of the hydro-electric plant was to generate electricity. The project seems to have deviated from its original purpose, which begs the question: What is the rationale for the Pumped Storage Project now?

- We support the idea of a study that explores the effects of deregulation, and would be interested in contributing to it.
- Regarding the stated intent to add more water to the storage area, we want to see objective, detailed studies of the projected impacts on the river, on water quality, on river ecology, and on streambank erosion. If the increase in storage capacity results in increased profits how will the utility pass along that benefit to affected communities and offset anticipated environmental impacts?
- We encourage FirstLight to seriously research a closed loop system for pumped storage facility.
- We acknowledge that mitigation of streambank erosion on both sides of the river in Northfield has been on-going, although often at a glacial pace that doesn't keep pace with the constant need for mitigation. We urge the utility to commit more resources and expertise to this work, rather than continue unproductive wrangling over the causes of the damage.

Thank you for this opportunity to address the Commission with our concerns.

Sincerely,

 Bill Llewelyn

Bill Llewelyn, Chair
Northfield Conservation Commission

Ashuelot River Local Advisory Committee

Washington Lempster Marlow Gilsum Sullivan Surry Keene Swanzey Winchester Hinsdale

Feb. 24, 2013

Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

Re: Northfield Mountain Pumped Storage Project, FERC Project No. 2485
Turners Falls Hydroelectric Project, FERC Project No. 1889

Dear Secretary Bose:

The Ashuelot River Local Advisory Committee (ARLAC) was established in 1994, one year after the Ashuelot River was enrolled into the New Hampshire Rivers Management and Protection Program. Members are nominated by Ashuelot River corridor municipal officials and appointed by the Commissioner of the NH Department of Environmental Services. ARLAC's mandate is to review and comment on projects within the corridor that have potential impacts on the river. We also have created, with acceptance by corridor towns, a Corridor Management Plan established in 2001 and updated in 2006. It is in this capacity that we wish to comment on the Pre-Application Document (PAD) submitted by First Light for the Northfield Mountain and Turners Falls Hydroelectric projects.

ARLAC has been supportive of the migratory fish programs implemented by NH Fish and Game as well as the Connecticut River Atlantic Salmon Commission. We support the installation of mechanisms that provide for upstream and downstream passage of diadromous fish in the Ashuelot, and have concern for the ability of these species to make their way from the Ashuelot watershed spawning habitat to the ocean, and their return from the ocean to the Ashuelot to spawn. Dams severely limit access to spawning habitat, and the proper operation of fish ladders is imperative to successful migration patterns of American eel, Sea lamprey, American shad, and Blueback herring. Dams also impact the natural movement of resident species. Along with supporting the proposed studies (noted in section 5.1.4) on the efficacy of the existing fish passage systems as listed in the PAD, consideration should be given to year-round operation of these facilities to enable both resident and migratory species to move freely throughout the river system.

Wide and frequent fluctuations in water levels not only increase sedimentation from erosion of the stream banks but can also dry out nesting areas, preventing successful fish breeding. Low water levels may also limit the ability of fish to reach tributaries for spawning, foraging, and shelter. Additionally, invasive plants are more tolerant than native species to fluctuating water levels; this leads to monocultures of invasive plants – which are of little benefit to native wildlife – in otherwise natural riparian habitat. With these issues in mind we support the proposed studies (noted in 5.2.5.1 & 5.1.6) of the effects of the Turners Falls Hydroelectric Project and Northfield Mountain Project operations on wetland, riparian and littoral zone habitat within and adjacent to their project boundary, with a baseline inventory of botanical resources to include the confluence with the Ashuelot River. Consideration of run-of-river mode for the Turners Falls Hydroelectric Project and perhaps a closed loop system of reservoirs for the Northfield Mountain project should be evaluated.

Respectfully submitted,
Barbara Skuly, Chairman

To: Federal Energy Regulatory Commission
RE: Comments on FERC Relicensing Projects: No. **P- 2485-063** (Northfield Mountain Pumped Storage Project) and No. **P-1889-081** (Turners Falls Hydroelectric Project)

Dear Commissioners,

Please carefully adhere to the standard FERC relicensing processes and deadlines as you relicense these two projects. Holding public and agency site visits in early October 2012 may have been deemed convenient for circumventing winter weather that might have affected visits, however it placed invested parties in the difficult position of having to view and judge hydro operations and configurations at both facilities without the benefit of knowing what operational changes and information FirstLight Power Resources was including in its PAD.

Further, of the three FERC group tours at Northfield/Turners Falls, only one group, mine, was able to view the area of the By-Pass Reach and the Turners Falls Canal and head gates from the downstream side of the Turners Falls gate house. This is a critical area to view, and the excuse being given was that there was construction happening on the Turners Falls Bridge. However, unrestricted access to view these sites was available to any passing citizen just yards away via a bike and walking path, open to the public. My group only received access because I made a direct request to FirstLight's John Howard, who was my former boss.

The two other tour groups did not get to see the confused flows created by the 14 head gates at the upstream end of the Turners Falls Canal. The canal has been a major disappointment as the upstream conduit for all migratory fish these last 34 years. Those head gates are open at full bore during much of the upstream fish migration season, they should have been a key component of the tour. Nor did interested parties get to view the exposed rock bed and de-pauperizing flow regimes created by flood gate manipulations at the Turners Falls Dam that renders the By-Pass Reach a non-river. FERC should place particular emphasis on any studies that redirect upstream migrating fish away from the confused and failed conditions experienced in the Turners Falls Power Canal, and send them directly upstream to a lift at TF Dam. That configuration has worked quite effectively at Holyoke Dam these last 58 years.

In late January 2013, GDF-Suez FirstLight Power Resource representative noted at public hearings that it intends to apply to FERC with a Proposed Study Plan to begin its own investigations of flows in the reach below Turners Falls Dam this April 2013, rather than the 2014 and 2015 study seasons noted in the FERC Relicensing Process. No study in this critical segment of river known as the By-pass Reach should be undertaken without a full vetting of the proposals. This section of river is critical spawning habitat for the federally-endangered Connecticut River shortnose sturgeon, also listed as endangered under the Commonwealth of Massachusetts Natural Heritage and Endangered Species Act. It is also the age-old upstream route for spawning federal-trust American shad and blueback herring. It is noteworthy that in their expedited study application that FirstLight cites the area below Cabot Station as a key shortnose sturgeon spawning location, while the critical site for these fish—used for likely thousands of years, is the natural escarpment in the riverbed known as Rock Dam, a half mile upstream of Cabot Station.

In a letter from FERC to Mr. John Howard of FirstLight Power Resources dated March 12, 2010, the Commission noted that FirstLight had failed to comply with Article 34 of the license for the

Turners Falls Project, releasing just 120 cubic feet per second to this segment of the river to protect shortnose sturgeon from the effects of low flows. The minimum requirement is 125 CFS.

With respect to measured, in-depth, long-term investigations on flow and river regulation in this reach I would direct you to the 17 years of research done by Dr. Boyd Kynard and colleagues at the Conte Anadromous Fish Research Center adjacent to this river segment in Turners Falls, MA. The work was largely conducted via the federal Conte Lab under the US Fish & Wildlife Service and later, under the US Geological Survey, when it took over responsibilities for Conte Lab after 1999. These investigations were also supplemented by funds, research and personnel from the University of Massachusetts at Amherst.

This research is documented in: ***Life History and Behaviour of Connecticut River shortnose and other sturgeons***, published in 2102 by the World Sturgeon Conservation Society and produced by Books on Demand, GmbH, Norderstedt, Germany: ISBN 978-3-8448-2801-6. Copies can be obtained from the **North American Sturgeon and Paddlefish Society**: www.nasps-sturgeon.org/#!/publications Chapter 3 concerns the long-term study of flows and river regulation on spawning success of the last 300, spawning-capable, federally endangered shortnose sturgeon in this river system—covering the period of 1993 – 2005. This is critical, long-term research that includes seven years of findings from the time before Northfield Mountain Pumped Storage and Turners Falls Hydroelectric Project operated as a regulated utility, and the seven years when Northfield’s pumping was unconstrained by regulations and operated to profit from price spikes and drops in the energy spot market using the public’s river. Deregulation was fully implemented here in 2000 or thereabouts. All of these issues need careful consideration before sanctioning a rushed study plan in such a critical river reach.

When considering a new license for these facilities, careful consideration of the public’s interest should be made respecting the changes and power generation, flows, and operational practices from the commencement of the current licenses down to the present. In 2012, Northfield Mountain Station added 40 megawatts of power to its generating facilities through retooling two of its turbines. This increase nearly equals the total power generated at HG&E’s Holyoke Dam, the next downstream project licensed by FERC. Two remaining turbines await power up-rates, which is a considerable addition to the generation at this plant, originally proposed and installed at 1,000 megawatts. Currently, due to mid-license changes, it now produces 1,119 megawatts of power in an unregulated power market.

Also noteworthy and important to be considered in weighing the public’s right to a living ecosystem, upstream fish passage, and protection of endangered species, is that Northfield Mountain’s original license was for a plant used to create “peaking power, and as a reserve unit.” It can only produce 6-8 hours of stored power before it is spent and needs to purchase replacement power on the open market. Its stated intention was to peak twice daily in high-demand winter and summer months, and once a day during shoulder months in spring and fall when energy demand is low. Northfield now generates when demand is present, or—when energy prices will make the greatest profit for investors. The river and the states have been impoverished by this profound change.

The building of Northfield was based on the availability of current and proposed power from collected regional nuclear sources (New England Power Pool) that included Maine Yankee (closed 1997); Yankee Rowe (closed 1992) Connecticut Yankee’s Haddam Neck (closed 1994), as well as two proposed nuclear plants at Montague, MA (never built.) Vermont Yankee is currently the only “local” nuclear plant still operating, and its 40 year operating license expired March 21, 2012. Its continued operation is contingent on findings in the courts. It is currently

operated at a loss by Entergy, and has a failing condenser system which could force its closure. In short, Northfield is now operated well beyond the bounds of its originally stated purpose. The public's river is paying a high price for power, much of it now imported to pump river reserves uphill to Northfield's reservoir from sources outside the region. The ecological impacts to fish runs and the damaging flow regimes imperiling endangered species in the river are apparent.

As a facility with great ecological impacts that cannot produce any of its own power--one totally dependent on outside sources for power, one proposed for using this stored power source put before the Federal Power Commission in the 1960s was that Northfield not operate during the spring fish migration due to its impacts on the runs. It is time to revisit the option of silencing the effects of Northfield Mountain so that towns and cities including Greenfield, Montague, Gill, Turners Falls, and Northfield, MA; and all the towns north to Vernon, Brattleboro and Bellows Falls, VT, and Hinsdale and Walpole, NH receive their share of the river's ecological bounty.

Northfield does serve a function as an emergency "reserve unit" for ISO New England (Independent Systems Operator) during times of severe heat waves, or high winter demand, to deliver a high volume of power on short notice to accommodate spikes in the power grid. Northfield could be taken off-line and kept in reserve to be operated by ISO New England solely for that purpose during the low-demand spring energy months when fish are migrating. This would greatly benefit river ecology, species, and all upstream stakeholders. New England's power grid resources are currently rated at 15% above demand. Removing the damaging effects of these operations on river ecology during critical months is a simple, equitable solution.

Northfield and Turners Falls have greatly profited by incremental power increases and operational changes over the past 34 years, while the public has watched flows, regulation, and conditions in the By-pass Reach wither to a brutal, feast-or-famine regime that denies spawning for endangered fish, and passage for upstream migrants. This situation has effectively privatized the 2-1/2 miles of river, depriving my town, Greenfield, as well as Gill, of its share of fish and a river. This de-pauperization has impacted all the towns upstream of Cabot Station and Turners Falls dam into central Vermont and New Hampshire. None of these municipalities have received compensation, though in many states the loss and damage to these fish populations would be considered "take" under state statutes. Damage in the By-Pass Reach to the Connecticut River's last 300, spawning-capable Connecticut River shortnose sturgeon carries a significant federal fine, as well as possible imprisonment.

FirstLight's new requests for more generation at both licensed sites should be rejected, and the damaging mid-license flow and power increases should be reversed in any new license. Indeed, since there have now been no less than FIVE different owner/operators of this facility in the last 14 years, it would be prudent to grant only the shortest license possible in order to help track and minimize damage to the ecosystem due to operational/managerial changes, and protect the public's interest in a living river.

Northfield's impacts have never been fully measured with respect to flows in the By-pass Reach, but it is clear that fish passage is now at, or below, the paltry levels of the 1980s, and just a fraction of the 40 – 60% passage upstream long-targeted by the US Fish & Wildlife Service of fish that had been passed at the Holyoke Fish Lift. Regulated, continuously monitored flows should be returned to the By-pass Reach at this time, and continuous monitoring should be included in any new licenses issued. FirstLight has noted that in-stream data loggers for river levels and flow have been subject to vandalism. Continuous camera monitoring of river levels and open and closed gate positions at the Turners Falls Dam would go

a long way toward insuring compliance with any new license conditions. This is an inexpensive solution that could easily include a back-up system.

With a federally endangered species present in the By-pass Reach, as well as federal-trust migrating American shad and blueback herring, FERC would do well to consider enforcing regulated flows in this stretch in accordance with law and statutes in the current license. NOAA's National Marine Fisheries Service has had the USGS Conte Lab findings from studies in the By-Pass reach by Kynard et al, in their possession since 2007. This agency—as well as the MA Division of Fisheries and Wildlife, could intervene at any time. These impacts are also affecting the success of the federal/state Connecticut River Migratory Fisheries Restoration, begun in 1967, which stipulates that all the states share equally in the bounty of migratory fish—as both a recreational and seafood resource. In several studies by the Massachusetts Cooperative Fisheries Unit at UMass/Amherst from the 1980s it is noted that blueback herring, (*Alosa aestivalis*) were noted gathering at the base of Turners Falls Dam, and were also noted spawning in the mouth of the Fall River—just 300 feet downstream of the dam, by then Conte Lab Director Steve Rideout.

Further, in the late 1980s, in another mid-license power up-rate, up to 5,000 CFS was redirected out of the By-pass Reach and into the Turners Falls Power Canal for use by Cabot Station and a refurbished Unit # 1, some 1-1/2 miles upstream of Cabot. This was undoubtedly another blow to the shortnose sturgeon attempting to spawn at their ancient grounds at the Rock Dam, though sturgeon spawning in the Connecticut here was not confirmed until 1993.

In the PAD, it is noted that FERC had not found any compliance issues during its inspections these two projects. However, as well as a failure to release minimum flows for sturgeon in 2009, I would direct you the US Environmental Protection Agency's August 3, 2010 letter and Administrative Order Docket No. 10-016, sent to Mr. James Ginnetti, FirstLight Vice President, noting violations of the federal Clean Water Act. FirstLight knowingly dumped up to 45,000 cubic square yards of silt into the Connecticut River below its fouled pumped storage plant in an attempt to clear its tunnels and intake. This illegal enterprise was undertaken by FirstLight after failing to conduct silt removal in a manner consistent with the "due diligence" stated in its operating license. This dumping took place throughout upstream fish migration season, May 1, 2010, or thereabouts, and continued until the EPA Cease and Desist Order of August 2010. At that time, FERC then became involved in this egregious license violation, requesting a full report from Mr. John Howard, Plant Manager, in a FERC letter dated August 10, 2010.

In a subsequent fall meeting with agency and non-profit river interests, a FirstLight representative stated that they did not know how to remove silt from their upper reservoir, and that it had never been done successfully. That admission came after 40 years of operating their plant. Hence, the public, and FERC are being asked to grant a new license to operators who have not shown they can successfully maintain their facility without profoundly affecting a navigable four-state waterway and a migratory fish highway. FirstLight has now asked for deadline relief, and is promising to have a study of siltation completed in 2014. Perhaps all study decisions should be held in abeyance until that time, 2014—which would comply with FERC Licensing Guidelines.

Sincerely,
Karl Meyer

RE: Northfield Mountain Pumped Storage Project, FERC Project No.2485,
Docket p-2485, sub docket 63

Dear Secretary Bose,

As president of the Massachusetts Farm Bureau Federation I represent approximately 6,000 members statewide. It is on behalf of these members that I write to you concerning issues with water withdrawals by farmers, and the permitting of First Light Power Generation for their operation on the Connecticut River in Massachusetts.

The issue boils down to the permit, and the authority given to the holder in allowing or disallowing other parties to withdraw water from the river. Under the provisions of the previously issued permits for this facility (held by a number of different entities), this has been a contentious issue with local farmers and was tied up in an ongoing legal exchange. Farmers are legitimately concerned that the license holder would prohibit them from withdrawing water during periods of drought, putting crops, livestock, and the farmer's livelihood at risk.

It would seem inherently unfair to that one private party would be granted decision-making power over another in determining which has access to public, natural resources. A better alternative would be to defer to existing state statutes and regulations in Massachusetts governing water withdrawal. The Massachusetts regulatory system relative to water withdrawals is objective and designed to balance the need for water withdrawal against environmental concerns and between parties competing for water access.

We ask that you do not include provisions in the above-mentioned permit which would allow the holder to govern water withdrawals. Instead, we ask that you defer to the regulatory system already in place and governed by the Commonwealth of Massachusetts.

On behalf of the agricultural community in Massachusetts, I appreciate your consideration.

Sincerely,

A. Richard Bonanno, Ph.D.
President

RE: Turners Falls Project 1889-081 & Northfield Mountain Pumped Storage Project
2485-063

Dear Commission;

I am a concerned resident that own property along the river. I am concerned for the future of this beautiful natural resource, as well as the existence along the rivers banks.

I have attached photos of my property, I strongly favor research into a "closed loop" system, it would be a man-made reservoir that would no longer involve the river for the generation of electricity.

Thank you for your time.

River Resident

RE: Comments on FirstLight Power Resources Notice of Intent to File License Application and Filing of Pre-Application Document for the Turners Falls Hydroelectric Project (No. 1889) and Northfield Mountain Pumped Storage Project (No. 2485)

Dear Secretary Bose,

On December 21, 2012, you issued a Notice of Intent to file a license application, filing of Pre-Application Document (PAD), commencement of pre-filing process, and scoping; request for comments on the PAD and Scoping Document, and identification of issues and associated study requests by FirstLight Power Resources (P-1889-P-2485). The PAD contains information about the project itself and the environmental resources that are affected by the project. As part of the Integrated Licensing Process, we (the National Marine Fisheries Service (NMFS)) have an opportunity to comment on the PAD and to submit study requests.

Attached for filing, please find our comments regarding the PAD. In addition, we are including fourteen requested studies. If you have any questions or need additional information, please contact Bill McDavitt (William.Mcdavitt@noaa.gov) or 978-675-2156 or Jessica Pruden (Jessica.Prudena@noaa.gov) or 978-282-8482.

Sincerely,

Louis A. Chiarella

cc: Service List

National Marine Fisheries Service's Comments and Study Requests on FirstLight Power Resources Pre-Application Document for the Turners Falls Hydroelectric Project (FERC No. 1889) and Northfield Mountain Pumped Storage Project (FERC No. 2485)

February 27, 2013

1 PROJECT BACKGROUND

The Turners Falls Hydroelectric Project (P-1889) is located at approximately river mile 122 on the Connecticut River. The Turners Falls Dam creates the Turners Falls Impoundment, which is approximately 20 miles long and extends upstream to the base of Vernon Dam. At the southwest end of Turners Falls Dam is the gatehouse. Below the dam, originating at the gatehouse is the Turners Falls power canal. Parallel to this power canal is the bypassed section of the Connecticut River. The power canal is associated with two hydroelectric generating facilities: Station No. 1 and Cabot Station. Station No. 1 is located approximately one-third of the way down the power canal. Water is conveyed from the power canal to a small branch that feeds the Station No. 1 turbines before discharging into the bypassed reach of the Connecticut River. Cabot Station is located at the downstream terminus of the power canal where the canal rejoins the main stem of the Connecticut River. Station No. 1 and Cabot Station discharge into the Connecticut River approximately 0.9 miles and 2.7 miles downstream, respectively of the Turners Falls Dam. Northfield Mountain Pumped Storage Project (NMPS) (P-2485) consists of an upper reservoir, an underground powerhouse and a tailrace that withdraws and releases water to the Turners Falls impoundment.

2 NOAA TRUST RESOURCES

We (NOAA's National Marine Fisheries Service (NMFS)) acts on behalf of the U.S. Department of Commerce (DOC) as a trustee for natural resources. We protect and restore aquatic organisms and their habitat on behalf of current and future generations of Americans.

We are a trustee for coastal and living marine resources, including commercial and recreational fisheries; diadromous species; marine mammals, and estuary and coastal habitat systems. Estuaries and coastal riverine habitat systems, including rivers such as the Connecticut River, provide an integral component of significant ecological functions for the larger marine environment. Many living marine resources are supported by estuaries and coastal rivers throughout their life cycles. Species such as endangered shortnose sturgeon (*Acipenser brevirostrum*), alewife (*Alosa pseudoharengus*), blueback herring (*Alosa aestivalis*), American shad (*Alosa sapidissima*), American eel (*Anguilla rostrata*), and sea lamprey (*Petromyzon marinus*) rely on these coastal systems for refuge, spawning, rearing and nursery habitat. NOAA's 2009-2014 National Strategic Plan (Strategic Plan) recognizes the significance of these resources in its mission goals, which include: "Protect, restore, and manage the use of coastal and ocean resources through an ecosystem approach to management." Historically, all these species were present within the Turner's Falls project reach. Currently, neither blueback herring nor alewives are found in this reach of the Connecticut River.

Overall, we are guided by three goals in carrying out these responsibilities as a trustee:

- Reducing threats to coastal resources and human health through planning and prevention;
- Protecting coastal resources and human health by recommending and implementing appropriate response actions; and
- Restoring injured trust resources

3 LISTED ENDANGERED SPECIES IN THE PROJECT AREA

Shortnose sturgeon

Shortnose sturgeon are listed as endangered under the Endangered Species Act of 1973, as amended (ESA). The species is listed throughout its entire range, with populations occurring in several rivers along the Atlantic coast. As noted in the Preliminary Application Document (PAD), endangered shortnose sturgeon inhabits the Connecticut River downstream of the Turners Falls Dam to Long Island Sound. Turners Falls is believed to be the historic upstream boundary of shortnose sturgeon in the Connecticut River (Kynard *et al.* 2012a) and there have been only a few anecdotal sightings of sturgeon upstream of the dam. Currently, the Connecticut River population of shortnose sturgeon is separated into an upstream and downstream segment bisected by the Holyoke Dam: upstream in a 36.9 mile reach between the Turners Falls and the Holyoke Dam, and downstream in a 87.5 mile segment between the Holyoke Dam and Long Island Sound. While literature indicates that shortnose sturgeon were separated following construction of the Holyoke Dam, recent behavioral and genetic information indicates shortnose sturgeon in the Connecticut River are of a single population impeded, but not isolated, by the dam (Kynard 1997, Wirgin *et al.* 2005, Kynard *et al.* 2012a) Individuals upstream are typically found as far north as river mile (RM) 121.3, but adults have occasionally been reported at the base of the Turners Falls Dam (RM 123.8; Kynard *et al.* 2012a).

The two main shortnose sturgeon spawning sites in the Connecticut River are both located approximately 2.5 miles downstream of the Turners Falls Dam (Kieffer and Kynard 2012). Researchers refer to the main spawning site as “Cabot Station” because it occurs in the tailrace of the Cabot Station powerhouse (RM 120). This site is approximately 2.7 hectares (ha) in area and receives water from above Turners Falls Dam that is diverted through the power canal for the Cabot Station powerhouse. A secondary, smaller site (0.4 ha in area) is located at Rock Dam (RM 121.3). Rock Dam is a natural rock barrier located in the natural river reach flowing from the Turners Falls Dam (Kieffer and Kynard 2012). Although shortnose sturgeon early life stages (ELS) have been captured downstream of the Holyoke Dam, evidence indicates that only minimal spawning occurs, leaving the Montague reach (RM 119.9-120.5) home to the primary spawning recruitment sites for the entire river.

Researchers have studied shortnose sturgeon spawning at these sites for 17 years (Kieffer and Kynard 2012). Spawning females restrict movement to a small area and females require 20 plus hours to spawn with egg deposition continuing until completion (Kynard *et al.* 2012b). Researchers used the following as indicators of successful or likely spawning: 1) ELS were captured at the site identified by tracked females verifying spawning success; 2) females restricted movement and were located repeatedly for 20 or more hours on suitable substrate and velocity habitat or a location where spawning had previously been identified; and 3) on-site locations of females occurred within the spawning period as defined by ELS captures (Kieffer

and Kynard 2012). Spawning suitability windows were defined using day length, temperature, and discharge data and described ranges of environmental conditions under which all spawning activity was observed. Temperature loggers were used to define temperature suitability and U.S. Naval Observatory data were used to identify day length. Discharge suitability had to be defined differently between both spawning sites due to the data available. For some years discharge data were available from the Northeast Utilities Service Co. (NUSCo), for other years USGS gauge data and modeling were used to identify discharge conditions and suitability (Kieffer and Kynard 2012). Day length and discharge were identified as the two most critical factors influencing the timing of shortnose sturgeon spawning in most years. However, within the appropriate day length window, discharge and temperature windows also had to be open simultaneously for spawning to occur. High spring discharge or brief increases in discharge (spikes) in excess of the suitability window during ongoing spawning activity delayed or stopped spawning.

Continuous monitoring between 1991–2007 revealed spawning succeeded at the Cabot Station site 71% of years and at the Rock Dam site, 21% of years. When spawning failed, it was due to river regulation, which created bottom velocities either too low or too high, or created discharge so low that females were either unable to reach or not attracted to spawning sites (Kieffer and Kynard 2012). Tagged pre-spawning adults arrived at Montague as early as 13 April and departed by 1 June. In years where spawning succeeded, adults remained at the Montague spawning sites as long as 4 weeks, though actual spawning periods were short (approximately 3–17 days). In successful spawning years, 1–324 ELSs were captured each year in anchored D-net sampling. Spawning periods, back-calculated from estimated ages of sampled ELS, occurred between 27 April and 22 May. In all years, spawning occurred as river temperature was increasing and river discharge was decreasing. During estimated spawning periods, daily mean temperature ranged from 6.5–15.9 °C and daily mean discharge ranged from 901–121 m³/s. All spawning occurred during photo-periods of 13.9–14.9 hours (corresponds with 27 April–22 May). From 1993–1995, researchers measured bottom velocity and depth on spawning sites over 24-h sampling periods (Kieffer and Kynard 2012). Mean spawning depths (for both sites) were 1.8m (range; 1.2–5.2m) and mean bottom velocities of 0.7m/s (range 0.3–1.2m/s). Both sites occurred in areas of swift water resulting in rubble substrate continuously swept clean of fine particles and algae.

Candidate species

Candidate species are those petitioned species that are being considered for listing as endangered or threatened under the ESA, as well as those species for which we have initiated an ESA status review that has been announced in the *Federal Register*. "Candidate" status does not carry any procedural or substantive protections under the ESA. Two candidate species, alewife and blueback herring (collectively, river herring) historically occurred in the project area. We are currently conducting a status review of river herring to determine if either species warrants listing under the ESA. For more information on the status review process and river herring please visit:

http://www.nero.noaa.gov/prot_res/CandidateSpeciesProgram/RiverHerringSOC.htm.

4 FEDERAL STATUTORY REQUIREMENTS

We are responsible for conservation, management, and protection of America's living marine and aquatic resources throughout jurisdictional river basins in coordination with other state and

federal agencies, local governments, Indian tribes, fisheries commissions, commercial and recreational fishers, and conservation organizations. Our authority to manage diadromous fish in these river basins comes from Congress. Specifically, Congress has directed us (NMFS) to manage diadromous species in river basins, including a grant of discretionary authority to us, to order fish passage at dams licensed by the Federal Energy Regulatory Commission. NMFS' congressionally mandated statutory authorities include the Federal Power Act, the Endangered Species Act, the Magnuson-Stevens Fishery Conservation and Management Act, the Atlantic Coastal Fisheries Cooperative Management Act, the Fish and Wildlife Coordination Act, and the National Environmental Policy Act.

4.1 The Federal Power Act (FPA) (as amended)(16 USC §§791a, *et seq.*)

Section 18 of the FPA - Section 18 of the FPA expressly grants to the DOC and the Department of the Interior unilateral authority to prescribe fishways. Section 18 of the FPA states that FERC must require construction, maintenance, and operation by a licensee at the licensee's own expense of such fishways, as may be prescribed by the Secretary of Commerce or the Secretary of the Interior. Within the DOC, the authority to prescribe fishways is delegated to the NMFS Regional Administrators.

Section 10(j) of the FPA - Under Section 10(j) of the FPA, licenses for hydroelectric projects must include conditions to protect, mitigate damages to, and enhance fish and wildlife resources, including related spawning grounds and habitat. These conditions are to be based on recommendations received from Federal and State fish and wildlife agencies. FERC is required to include such recommendations unless it finds that they are inconsistent with Part I of the FPA or other applicable law, and that alternative conditions must adequately address fish and wildlife issues. Before rejecting an agency recommendation, FERC must attempt to resolve the inconsistency, giving due weight to the agency's recommendations, expertise, and statutory authority. If FERC does not adopt a Section 10(j) recommendation, in whole or in part, it must publish findings that adoption of the recommendation is inconsistent with the purposes and requirements of Part 1 of the FPA or other applicable provisions of law, and that conditions selected by FERC adequately and equitably protect, mitigate damages to, and enhance fish and wildlife and their habitats.

Section 10(a)(1) of the FPA - Resource agencies may also recommend conditions under Section 10(a)(1) of the FPA for the protection, mitigation and enhancement of fish and wildlife (including related spawning grounds and habitat).

4.2 Endangered Species Act (ESA) (as amended) (16 USC §1531 *et seq.*)

Section 7(a)(2) of the ESA, states that each Federal agency shall, in consultation with the Secretary, insure that any action an agency authorizes, funds, or carries out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. Any discretionary federal action that may affect a listed species must undergo Section 7 consultation. Section 7(a)(1) requires Federal agencies to use their authorities to further the conservation of listed species. We expect that FERC, as the lead Federal agency, will initiate consultation with us on the effects of the proposed relicensing on listed species under our jurisdiction.

4.3 Magnuson-Stevens Fisheries Conservation and Management Act (MSA) (as amended) (MSA) (16 USC §§1801, *et seq*)

The 1996 amendments to the MSA set forth a number of mandates for us, the Fisheries Management Councils (Councils), and other Federal agencies to identify and protect important marine and diadromous fish habitats. The councils are required to identify and describe essential fish habitat (EFH) for all managed species in order to protect habitat from fishing impacts and to allow for consultation with federal agencies whose actions may adversely impact essential fish habitat. EFH is defined as “those waters and substrates necessary to fish for spawning, breeding, feeding or growth to maturity.” 16 U.S.C. § 1853(a)(7) and § 1802(10). The MSA requires federal agencies to consult with the Secretary of Commerce, through us, with respect to “any action authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken, by such agency that may adversely affect any essential fish habitat identified under this Act.” 16 U.S.C. § 1855(b)(2). In the EFH consultation process, the federal action agency initiates consultation by preparing and submitting a completed EFH assessment describing the potential impacts of the action on EFH.

4.4 The Atlantic Coastal Fisheries Cooperative Management Act (ACFCMA) (as amended) (16 USC §§5101, *et seq.*)

The purpose of the ACFCMA is to provide for more effective fishery resource conservation of coastal fish species that are distributed across the jurisdictional boundaries of the Atlantic States and the Federal Government. These coastal fish species, which include American eel, shad and river herring, are managed by various species boards of the Atlantic States Marine Fisheries Commission, which develop fishery management plans and recommend management action to the states and NMFS.

4.5 The Fish and Wildlife Coordination Act (FWCA) (as amended) (16 USC §§661, *et seq.*)

The FWCA provides that fish and wildlife conservation shall receive equal consideration and be coordinated with other features of water resource development programs. A Federal action agency, such as the Federal Energy Regulatory Commission (FERC), shall consult with us with a view to the conservation of fish and wildlife resources by preventing loss of and damage to such resources as well as providing for the development and improvement thereof in connection with such water resource development. We may provide recommendations to the Federal action agency to which the action agency shall give full consideration.

4.6 The National Environmental Policy Act (NEPA) (as amended) (42 USC §§4321, *et seq.*)

The NEPA of 1969 (42 USC §§4321 *et seq.*) and its implementing regulations require Federal action agencies to analyze the direct and indirect environmental effects and cumulative impacts of project alternatives and connected actions. The NEPA requires the Federal action agency to conduct a comparative evaluation of the environmental benefits, costs, and risks of the proposed action, and alternatives to the proposed action.

4.7 Policy and coordination

Based on the above listed laws, we have developed policies designed to implement these laws.

4.7.1 NOAA Strategic Plan

To achieve this mission, NOAA's Next Generation Strategic Plan identifies the Habitat program for the protection and restoration of coastal marine habitats that support NOAA trust resources. An important objective of the Habitat program is to "improve ecosystem health through conservation and restoration of habitat." Our strategic plan further identifies the Protected Resources program to protect and work to recover species at risk of extinction, and the Fisheries Management program to ensure maintenance of fisheries at productive levels for supporting sustainability and the ecosystems to which they contribute. Strategies utilized to achieve this objective include implementing cooperative approaches at the local level in habitat conservation and restoration, including greater involvement in the review of FERC activities; and, by working to increase the survival of anadromous fish passing through hydroelectric facilities.

4.7.2 Atlantic States Marine Fisheries Commission (ASMFC)

The role of the ASMFC is to facilitate cooperative management of inter-jurisdictional fish stocks. ASMFC does this by creating Interstate Fisheries Management Plans for jurisdictional species. These plans set forth the management strategy for the fishery and are based upon the best available information from the scientists, managers, and industry. The plans are created and adopted at the ASMFC Policy Board level and the plans provide recommendations to the states and Federal government that allow all jurisdictions to independently respond to fishery conditions in a unified, coordinated way. The Atlantic Coastal Fisheries Cooperative Management Act requires the Federal government to support the ASMFC's management efforts. The Federal government enacts regulations to complement ASMFC recommendations when appropriate. To the extent the Federal government seeks to regulate an ASMFC managed species, those Federal regulations must be compatible with the ASMFC's plan and consistent with the 10 National Standards set forth in the Magnuson-Stevens Act.

The ASMFC has developed two plans that relate to our trust species. We highlight the plans' goals and recommendations below.

ASMFC's Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (2010)

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes

When considering options for restoring alosine habitat, NOAA should include study of impacts and possible alteration of dam-related operations to enhance river habitat.

This document includes the following recommendations:

General Fish Passage

- 1) States should work in concert with the United States Fish and Wildlife Service (USFWS) and the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NMFS) to identify hydropower dams that pose significant impediment to diadromous fish migration, and target them for appropriate recommendations during FERC relicensing.
- 2) States should identify and prioritize barriers in need of fish passage based on clear ecological criteria (e.g., amount and quality of habitat upstream of barrier, size, and status of affected populations). These prioritizations could apply to a single species, but are likely to be more useful when all diadromous species are evaluated together.
- 3) A focused, coordinated, well supported effort among federal, state, and associated interests should be undertaken to address the issue of fish passage development and efficiency. The effort should attempt to develop new technologies and approaches to improve passage efficiency with the premise that existing technology is insufficient to achieve restoration and management goals for several Atlantic coast river systems.
- 4) Where obstruction removal is not feasible, install appropriate passage facilities, including fish lifts, fish locks, fishways, navigation locks, or notches (low-head dams and culverts).
- 5) At sites with passage facilities, evaluate the effectiveness of upstream and downstream passage; when passage is inadequate, facilities should be improved.
- 6) Facilities for monitoring the effectiveness of the fish passage devices should be incorporated into the design where possible.
- 7) When designing and constructing fish passage systems, the behavioral response of each species of interest to appropriate site-specific physical factors should be considered.
- 8) If possible, protection from predation should be provided at the entrance, exit, and throughout the passage.
- 9) The passage facility should be designed to work under all conditions of head and tail water levels that prevail during periods of migration.
- 10) Passages are vulnerable to damage by high flows and waterborne debris. Techniques for preventing damage include robust construction, siting facilities where they are least exposed to adverse conditions, and removing the facilities in the winter.
- 11) Passage facilities should be designed specifically for passing alosines at optimum efficiency.

Upstream Fish Passage

- 1) American shad must be able to locate and enter the passage facility with little effort and without stress.
- 2) Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
- 3) Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.

Downstream Fish Passage

- 1) To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

Other Dam Issues

- 1) Where practicable, remove obstructions to upstream and downstream migration in lieu of fishway construction.
- 2) Locate water intakes where impingement/entrainment rates are likely to be lowest, employ intake screens or deterrent devices to prevent egg and larval mortality, and alter water intake velocities to reduce mortalities.
- 3) To mitigate hydrological changes from dams, consider operational changes such as turbine venting, aerating reservoirs upstream of hydroelectric plants, aerating flows downstream, and adjusting in-stream flows.
- 4) Natural river discharge should be taken into account when instream flow alterations are being made to a river (flow regulation) because river flow plays an important role in the migration of diadromous fish.
- 5) Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account instream flow needs for American shad migration, spawning, and nursery use, and minimize deviation from natural flow regimes.
- 6) When considering options for restoring alosine habitat, include study of impacts and possible alteration of dam-related operations to enhance river habitat.

The relicensing process for the Turners Falls and NMPS projects provides an excellent opportunity to incorporate many of the ASMFC recommendations.

ASMFC's Interstate Fisheries Management Plan for American Eel (2000)

The goals in this plan include the following:

1. Protect and enhance the abundance of American eel in inland and territorial waters of the Atlantic States and jurisdictions and contribute to the viability of the American eel spawning population
2. Protect and enhance American eel abundance in all watersheds where eel now occur
3. Where practical, restore American eel abundance in all watersheds where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Recommendations for Federal Energy Regulatory Commission Relicensing

The ASMFC recognizes that many factors influence the American eel population, including harvest, barriers to migration, habitat loss, and natural climatic variation. The ASMFC's authority, through its member states is limited to controlling commercial and recreational fishing activity; however, to further promote the rebuilding of the American eel population, the

ASMFC strongly encourages member states and jurisdictions, as well as the USFWS, to consider and mitigate, if possible, other factors that limit eel survival. Specifically, the ASMFC requests that member states and jurisdictions request special consideration for American eel, in the FERC relicensing process. This consideration should include, but not be limited to, improving upstream passage and downstream passage, and collecting data on both means of passage.

4.7.3 Connecticut River Atlantic Salmon Commission (CRASC)

The CRASC developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.

5 NMFS COMMENTS ON THE PRE-APPLICATION DOCUMENT (PAD)

Based on our review of the PAD submitted by FirstLight we offer the following comments.

5.1 PAD Section 3.2.3 Fish Passage Facilities

The applicant summarizes the CRASC established schedule for upstream and downstream passage facilities to be operational in Tables 3.2.3-1 and 3.2.3-2. We note that through existing fish passage agreements (memorandums of understanding) with previous owners and through FERC, the State and Federal agencies and CRASC have implemented an Annual Fish Passage Notification Letter to the main stem dam hydro-power operators. This letter is distributed to the identified owner/operators and explicitly states start and end dates of fish ladder, fish lift, fish bypass structures, gates, barrier nets, and other protective measures for the identified target diadromous species and for various life stages (e.g., adults/up, adults/down, juveniles/down). The Passage Notification letter is under the CRASC letterhead, signed by the Executive Assistant of CRASC. All dates of operation are noted as subject to change, based upon the request of the resource agencies and/or in consultation with the Licensee. Examples of recent changes to this schedule include the upstream passage operation start date for Vernon Dam fish ladder of April 15, which became effective in 2011. Other changes include the shift to start juvenile American shad downstream passage operations from September 1, to August 1 (effective in 2011). These changes reflect research study findings. With respect to upstream shad passage, recent changes in environmental conditions that may be part of a climatological trend led to the earliest upstream passage counts from the Turners Falls Dam in 2012. Such continued adjustments to the passage calendar will be important to ensure successful passage without causing delays for migratory fish.

The PAD describes the Northfield Mountain Guide Net. Given the proposed modifications to the Northfield Mountain project in section 3.4.4 of the PAD, neither this section nor section 3.4.4 (Proposed Modification) describes what changes, if any, are proposed for preventing impingement and entrainment of migratory and resident fish. Such information will be important when determining environmental impacts.

5.2 PAD Section 3.3.1 Operational License Requirements – Fishway Requirements

Table 3.3.1- 1 summarizes attraction flows for the three fishways associated with the Turners Falls project. Cabot Station has a maximum hydraulic capacity of 13,728 cfs. As percentage of maximum hydraulic capacity, the Cabot Fishway attraction flows are 2.4% for the maximum attraction flow. The PAD does not state any ladder attraction effectiveness for fish that may or may not enter the entrances to the Cabot or Spillway Fishways. We are unable to determine whether the present attraction flow is sufficient or if modifications may be required. FERC should order the applicant to provide information that indicates the effectiveness of fish entering both of their fishways on the existing auxiliary water system flows.

5.3 PAD Section 3.3.2 Turners Falls and Northfield Mountain Operations

The PAD summarizes the minimum, maximum and target elevations at the dam and in the power canal. It then goes on to summarize operations at various increasing flow ranges. Information on the statistical summary of current operation water levels such as a stage duration curve is needed. Given the proposed modifications in Section 3.4.4 (Proposed Modifications) we would like to know to what degree, if any, the stage duration curve may change under proposed conditions. We would also like to know the rate at which and when headpond elevations can change and what conditions might lead to rapid changes either increasing or decreasing. Given the migratory and resident fish that utilize the habitat in the headpond, we would like to have more information about the timing, magnitude and duration of potential headpond fluctuations. FERC should order the applicant to present how the existing flow duration curve would change under this proposal.

5.4 PAD Section 3.4.4 Proposed Modifications

The Licensee indicated their intent to use more storage in the NMPS project upper reservoir, and proposes to increase the unit and station capacity at the NMPS project. FERC should require the applicant to provide additional details and information on these proposals. Limited additional detail is provided. Given the impacts that existing operations have on the Connecticut River, we strongly urge FERC to fully take into consideration potential environmental impacts these proposals could cause to the Connecticut River and its resources during this relicensing process. As our study requests indicate, there are several significant information gaps regarding current operations. These information gaps will certainly apply if the proposed modifications are implemented.

5.5 PAD Section 4.2.4 Reservoir Shoreline and Streambanks

This section of the PAD summarizes the study efforts that have occurred on the Connecticut River within the Turners Falls project boundaries since 1979. The PAD makes reference to the 1991 Army Corps of Engineers (Corps) reconnaissance level mapping effort. This section does not identify some of the findings of this report which include the following:

“The results of this study show that riverbank erosion has increased almost threefold since 1979. Approximately one-third of the 148,000 linear feet of shoreline in this reach is undergoing some form of active erosion. In addition, the Turners Falls pool has remained the most dynamic pool on the Connecticut River, with daily fluctuations in water level averaging 3.5 feet...Recreational boating activity has also increased dramatically with the construction of public access points on the river.”

The 1991 report includes a section titled “Evaluation of Causes within the Study Reach” and goes on to state, “As noted in the 1979 report, the next most significant cause of erosion is pool fluctuations which can cause an increase in the instability on the order of 18 percent of the shear stress exerted on the bank by flowing water. The impacts of hydropower development on bank stability in Turners Falls Pool have been and continue to be more severe than for other hydropower pools studies in the 1979 report due to differences in operation.”

The 1991 report assigned percentages to each of the variables responsible for erosion. The Corps made these estimates for banks composed of non-cohesive material and for stratified material. In non-cohesive material, pool fluctuations and boat waves were responsible for approximately 27% of the erosion; in stratified material these two sources accounted for 30% of the erosion.

The PAD references the 2007 Field Geology Services Study which was submitted to the FERC compliance manager for Turners Falls and NMPS. The PAD summarizes some of the findings of this study, but the opening sentence in this report’s closing paragraph states “Given the complexity of issues surrounding erosion in the Turners Falls Pool the results of this study are considered preliminary. Several questions regarding the reliability of the earlier erosion mapping remain.” We still lack a clear understanding of the magnitude and causes of bank erosion in the Turners Falls headpond. Requested study #14 is designed to fill in this information gap.

5.6 PAD Section 4.4.5.2 Anadromous Fish Species below Turners Falls Dam – Blueback Herring

The PAD accurately reflects that we published a positive 90-day finding that the petition action to list alewife and blueback herring under the ESA may be warranted. We are currently conducting a comprehensive status review of the both species. The PAD presents biological data on blueback herring, though there is no information on alewives. Scientific data on both species should be included in the PAD. If fish passage improves at the Holyoke Dam due to future fishway modifications, alewives may be present in the vicinity of the Turners Falls project. The PAD does not contain any analysis of the effects of existing project operations on river herring and the effects of continuing operations and maintenance that would result from the proposed relicensing. It should do so.

5.7 PAD Section 4.4.6 Anadromous and Catadromous Fish Species in the Turners Falls Impoundment

Under the Cabot Station downstream subsection, the PAD references Brown 2009 and the high percentage of eels that pass the project via the turbines. This study also found that “at least 32% (9 out of 28) of the eels that used the turbines as a passage route at Cabot Station failed to continue their downstream migration and reach Hadley Falls Station. Downstream passage of large, pre-spawning females at multiple dams with this similar level of mortality will have severe cumulative effects on overall migrant eel survival and reproductive escapement.” The ASMFC’s policy is that FERC consider passage impacts to American eel at hydroelectric projects (ASMFC, 2000). Given that American eel have been petitioned to be listed as an endangered species, this level of mortality during the adult downstream passage season is a considerable concern for us.

5.8 PAD Section 4.4.8 Shortnose Sturgeon

The biological information presented on shortnose sturgeon in the PAD should be updated to include critical information in Kynard *et al.* (2012). The PAD does not contain any analysis of effects of existing project operations on shortnose sturgeon and the effects of continuing operations and maintenance that would result from the proposed relicensing. There is a large body of information on shortnose sturgeon in the Connecticut River. Specifically, there are significant scientific data available on shortnose sturgeon life history in the area between the Holyoke Dam and Turners Falls Dam. This information provides biological data on shortnose sturgeon spawning and rearing as well as the impact of project operations at the Turners Falls Hydroelectric Project on shortnose sturgeon. Given that shortnose sturgeon are known to be negatively affected by the Turners Falls Hydro Project operations, a complete analysis of effects is necessary.

6 REQUESTED STUDIES

We are requesting fourteen studies. Many of these studies are complex and will require additional coordination on the specific study design and methodology. FirstLight has directly engaged us and the other resource agencies to streamline development of the study requests and ensure timely implementation. Coordination commenced in 2011 and has continued throughout 2012 and 2013. FirstLight is hopeful that advanced coordination will allow them to begin modeling exercises during 2013, which should inform subsequent modeling and field studies. We support this approach. FERC and FirstLight should be aware that all scientific research targeting a species listed under the ESA requires a permit issued pursuant to section 10 of the ESA. A section 10 permit exempts the applicant from liability for take of a listed species provided the take is in the course of permitted activity. Study requests #2 and #3 seek field verification of modeling results. If the study design for these requests may result in take of any life stage of shortnose sturgeon, coordination with NMFS Headquarters Office of Protected Resources is required.

In addition to our requested studies listed below, we support the requested studies filed by the USFWS. In particular, the shad population model for the Connecticut River is an important study that will improve the resource agencies understanding of cumulative effects of the TransCanada and FirstLight projects on the Connecticut River.

6.1 Requested Study #1: Model river flows and water levels upstream and downstream from the Turners Falls Project generating stations and integration of project modeling with other project operations on the Mainstem Connecticut River

A river flow model can be designed such that it allows for an evaluation of the hydrologic changes to the river caused by the physical presence and operation of the Turners Falls Hydroelectric Project and the interrelationships between river inflows and the operation of all five hydroelectric projects up for relicensing (i.e., P-1889 Turners Falls Hydroelectric Project, P-2485 Northfield Mountain Pumped Storage, P-1904 Vernon Hydroelectric Project, P-1855 Bellows Hydroelectric Project, P-1892 Wilder Hydroelectric Project). Current modeling efforts and the associated data output already underway by the U.S. Geological Survey, U.S. Army

Corps of Engineers, The Nature Conservancy and University of Massachusetts at Amherst could potentially be used to help assist in this effort.

Goals and Objectives

The goal of this study is to determine the extent of alteration of river hydrology caused by operation of the project and the interactions between upstream project operations, Turners Falls operations and downstream operations at the Holyoke Project. The models will provide necessary information on what changes can be made to each of the five project's flow releases and/or water level restrictions, and how those changes affect downstream resources.

We anticipate other specific modifications to operations for each projects will be identified based on results of other requested studies. These conditions will need to be included in the models to assess how each change affects Turners Falls and other project operations, and the implications of those changes on other resources and/or the ability to achieve desired operational changes at other projects. Specifically, the Turners Falls Project has a required continuous minimum discharge flows in the Turners Falls bypass reach that need to be no less than 2,500 cfs during shortnose sturgeon spawning, rearing, and outmigration (April 15th – June 22nd). Incorporating these parameters into the model will inform what changes, if any, need to be made to operations of upstream projects to accommodate such flows.

The flow studies should assess the following topics:

1. Conduct quantitative hydrologic modeling of the hydrologic influences and interactions that exist between the water surface elevations of the Turners Falls Project impoundment and discharges from the Turners Falls Dam and generating facilities and the upstream and downstream hydroelectric projects. Data inputs to and outputs from the model(s) should include:
 - a. Withdrawals from the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project, FERC No. 2485;
 - b. Discharges to the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project;
 - c. Discharges into the Turners Falls impoundment from the Vernon Project, FERC No. 1904 and other sources;
 - d. Existing and anticipated discharges from the Turners Falls Project generating facilities and spill flows;
 - e. Existing and anticipated water level fluctuation restrictions (maximum and minimum pond levels) of the Turners Falls impoundment and downstream flows from the project;
 - f. Existing and anticipated required minimum flows and/or other operation requirements at each of the four upstream projects;
 - g. Minimum discharge flows ranging between 2,500– 6,300 cfs in the bypass reach from April 15th through June 22nd to support spawning, rearing, and outmigration of shortnose sturgeon at Rock Dam.
2. Document how the existing and anticipated outflow characteristics from the four upstream projects affect the operation of the Turners Falls Project including downstream flow releases and Turners Falls' impoundment levels.

3. Assess how operation of the existing Turners Falls Project and upstream projects affect Holyoke Project (P-2004) operations including:
 - a. How Turners Falls Project flow fluctuations affect Holyoke impoundment water levels;
 - b. How Turners Falls Project operations affect Holyoke Project discharges.
 - c. What changes in Turners Falls operations would be needed to reduce fluctuations in the discharges from the Holyoke Project.

Resource Management Goals

We seek to accomplish a number of resource goals and objectives through the relicensing process for this Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional diadromous fish and aquatic habitat objectives for the basin.
2. Conserve, protect, and enhance aquatic habitats for diadromous fish species that continue to be affected by the Project.
3. Assist FERC to ensure that future operation of the Project is not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources, our goals are:

1. Protect, enhance, or restore diverse high quality aquatic and riparian habitats for diadromous species in the watershed and mitigate for loss or degradation of this riverine ecosystem.
2. Provide an instream flow regime in the bypass reach that meets the life history requirements of diadromous fish and federally listed shortnose sturgeon.
3. Minimize current and potential negative project operation effects on water quality and aquatic habitat.
4. Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing within the Montague spawning area (i.e. Rock Dam and Cabot Station spawning sites and associated early life stage rearing areas).

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Information in the PAD does not indicate how project operations have altered downstream hydrology, which may affect diadromous species and endangered shortnose sturgeon and other natural processes in the Connecticut River from below the Vernon Dam downstream to the Holyoke Dam.

Information in the PAD also does not reflect data analyzed in Kynard *et al.* (2012), which identifies minimum discharge thresholds for shortnose sturgeon spawning and rearing at the Rock Dam spawning site. Spawning success was observed at Rock Dam when discharge was

between 2,500 cfs and 22,000 cfs during the spawning period (April 27–May 22nd) (Kieffer and Kynard 2012). In 1995, at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 ELS captured, spawning period was 17 days) even though no spawning was detected at Rock Dam (Kieffer and Kynard 2012). Discharges in 1995 at Rock Dam had dropped below 2500 cfs (i.e., by March 26th) before the spawning period of April 27th (Kieffer and Kynard 2012), showing that even though 1995 saw the largest number of pre-spawning adults, none spawned at the Rock Dam. This may indicate the need to have adequate flow well in advance of spawning. Discharge reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning site and not return even if flow increased to acceptable levels later during the spawning period. Researchers observed that substrate did not change during fluctuating flows and thus, cessation of spawning is likely due to velocities falling below the range preferred by females. Given the current flow dynamics at Rock Dam that do not provide adequate attraction flows and flows necessary for spawning; spawning does not occur most years at Rock Dam (Kieffer and Kynard 2012). These data represent the best available scientific information and indicate that the current minimum flow thresholds (i.e., minimum bypass flow (400 cfs from 5/1 through 7/15; 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flow below the projects of 1,433 cfs) at the project are not adequate for the protection of endangered shortnose sturgeon. All modeling efforts described above must incorporate the identified minimum flow and temporal parameters. These study requests are designed to identify the minimum flows and temporal parameters necessary to protect shortnose sturgeon.

Project Nexus

The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (400 cfs from 5/1 through 7/15; 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flow below the projects of 1,433 cfs. The project operates as a daily peaking project, often with large, rapid, daily flow fluctuations between the minimum and project capacity (15,928 cfs) and fluctuations in headpond elevation (175' to 186' MSL). These changes affect biotic habitat and biota upstream and downstream of the Turners Falls project. Project operations and potential changes to operations to mitigate impacts to aquatic habitat and diadromous species at the Turners Falls Hydro Project, are influenced by inflows and operations of the upstream Trans Canada peaking Hydro projects and the Northfield Mountain Pumped Storage Project operations. Potential changes in operations of each of both the First Light and Trans Canada Projects, could affect the ability to achieve desired operational changes. Results of river flow analyses will be used to develop flow-related license requirements and/or other mitigation measures.

Proposed Methodology

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess implications of project operations on the river environment.

Level of Effort and Cost

Level of effort and cost of model development are expected to be moderate but to be valuable in developing license conditions, the model(s) will need to be run under various scenarios throughout the relicensing process to assess the implications of changes to the operations of each project on other projects and other resources. Therefore, ongoing consultation and re-running of the model(s) are likely to be needed throughout the relicensing process. The modeling exercise

will also require coordination and cooperation between FirstLight and the upstream licensee to assure that the model inputs and outputs can be accurately related. The lack of such coordination may lead to results that are not truly representative of anticipated discharge flows under varying operations scenarios.

We would anticipate that the expected level of effort and anticipated costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., Conowingo, FERC No. 405).

One alternative to developing numerical hydraulic model is to develop a physical model of the river and associated structures. The level of effort to develop a physical model would be too time-consuming and cost prohibitive.

6.2 Requested Study #2: In-stream flow habitat assessment downstream of Cabot Station

We recommend the applicant conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species. The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species and benthic invertebrate communities. Target fish species include: federally endangered shortnose sturgeon, American shad, American eel, and sea lamprey.

Goals and Objectives

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources from the Cabot tailrace of the Turners Falls Project downstream to the Rt. 116 Bridge in Sunderland, MA. The objective of the study is to conduct an instream flow habitat study to assess the impacts of a range of flows on the wetted area and optimal habitat for key species, including the impacts of hydro-peaking flow fluctuations on the quantity and location of aquatic habitat.

For shortnose sturgeon, the flow study will need to evaluate bottom velocities in spawning and rearing areas during discharge conditions observed from April 15th to June 22nd. Protection of shortnose sturgeon spawning will necessitate establishment of discharges that create bottom velocities suitable for spawning and rearing over a sustained period of time and avoid dramatically fluctuating flows. To protect shortnose sturgeon rearing, adequate discharge without dramatic flow fluctuations are needed to ensure the rearing shoals are wetted and velocities are sufficiently protective for early life stage (ELS) rearing.

Field verification will be necessary to confirm the flow modeling results that identify the flows needed to provide sustained bottom velocities for spawning and also maintain flows, depths, and water release regime adequate for spawning and rearing. Velocity and depth data should be collected under each potential operation scenario such that actual velocity, depth, and flow conditions occurring across the entire spawning and rearing areas including wetted shoals are documented.

Resource Management Goals

We seek to accomplish a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional diadromous fishes and aquatic habitat objectives for the basin.
2. Conserve, protect, and enhance aquatic habitats for diadromous fish species that continue to be affected by the Project.
3. Assist FERC to ensure that project operations are not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources, our goals are to:

1. Protect, enhance, or restore diverse high quality aquatic and riparian habitats for diadromous species in the watershed and mitigate for loss or degradation of this riverine ecosystem.
2. Provide an instream flow regime in the bypass reach that meets the life history requirements of diadromous fish and federally listed shortnose sturgeon.
3. Minimize current and potential negative project operation effects on water quality and aquatic habitat.
4. Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing within the Montague spawning area (i.e. Rock Dam and Cabot Station spawning sites and associated early life stage rearing areas).

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Presently, FirstLight is required to release 1,433 cfs below the Project. Information included in the PAD does not provide a detailed description of how this minimum flow was established and we are not aware of any previously conducted studies that evaluated the adequacy of this minimum flow in protecting aquatic resources in the 10+ miles of riverine habitat below the Cabot Station. Therefore, an empirical study is needed to provide information on the relationship between flow and habitat in the Connecticut River downstream of the Cabot tailrace. We will use the results of this study to determine an appropriate flow recommendation.

Kieffer and Kynard (2012) examined the effects of water manipulation at the Turners Falls project on shortnose sturgeon spawning over the course of 17 years. This study represents the best available scientific information and does not support 1,433 cfs as an adequate minimum flow to support successful shortnose sturgeon spawning at Cabot Station. Peaking operations at Cabot Station cause discharge fluctuations to rapidly change bottom velocities from 0.4 m/s to 1.3 m/s over 30 minutes (Kieffer and Kynard 2012). Shortnose sturgeon have not evolved to adapt to such rapid changes in velocities and therefore, continue to spawn during fluctuations even though conditions may be unsuitable and likely result in high egg mortality. During the 10 years when spawning succeeded at Cabot Station, discharge flow decreased to less than 35,460 cfs by April 29th. The lowest discharge level observed while females remained on the spawning site was 4,700 cfs. Spawning behavior was not monitored during Cabot Station discharges at or

below 3,500 cfs, so it is unclear what the minimum flow threshold is for spawning at Cabot Station. When peaking generation discharges ceased during naturally low flow years, the tailrace shoals, likely used by shortnose ELS for rearing, were exposed (observed during years '95, '98-99, '04) and may have resulted in larva mortality due to stranding and exposure (Kieffer and Kynard 2012). Researchers observed that shoal exposure began when river flow below Cabot Station dropped below 7,062 cfs (Kynard and Kieffer 2007). Thus, total flow at Cabot, which may include flow from the Turners Falls Dam or Station 1, must be at least 7,062 cfs to both support adequate bottom velocities and prevent shoal exposure.

Furthermore, the emergency water control gates at Cabot Station used to sluice trash from the canal and balance canal flows spill large amounts of water. These large spill events create a plume of turbid, turbulent flow, causing some females to leave the area. These spill events scour bottom sediments which are then carried downstream over the spawning and rearing shoals where an entire year class of early life stages may be destroyed (Kieffer and Kynard 2012). Information included in the PAD does not address adequate flows for shortnose sturgeon spawning and rearing. Results of the requested modeling will be used by us to determine an appropriate flow recommendation for shortnose sturgeon.

Researchers have also looked at suitable depth and velocity habitat for shortnose sturgeon spawning (Kynard and Kieffer 1996, Kieffer and Kynard 2012). Spawning sites are characterized by moderate river flows with average bottom velocities between 0.4 and 0.8 m/s (Hall *et al.* 1991, Kieffer and Kynard 1996, NMFS 1998). Water depth at the spawning site appears to be a less important habitat feature than substrate type and flow. This information should be considered when modeling flow regimes that are sufficiently protective of shortnose sturgeon spawning and rearing. In addition, although eggs and embryos can likely tolerate very shallow depths, researchers measuring water depths between Turners Falls Dam and Cabot Station with the intention of recommending water depths suitable for shortnose sturgeon trapped in the Turners Falls Dam Plunge Pool recommend an escape route be used that is 1.5 times the maximum body depth. Because adults spawning in an artificial spawning channel frequently positioned themselves on top of one another (Kynard *et al.* 2012b), a minimum depth to facilitate spawning within the known Cabot Station spawning area is 3.0 body depths.

Project Nexus

The Turners Falls Project is currently operated with a minimum flow release that was not based on biological criteria or field study. Further, the project generates power in a peaking mode resulting in significant with-in day flow fluctuations between the minimum and project capacity on hourly or daily basis. The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project. Shortnose sturgeon larval migrants initially become bottom dwellers and transition from living off of yolk sacs to orally feeding, which is a critical stage in their life history. While the existing license does require a continuous flow of 1,433 cfs below the project (0.20 cubic feet per second flow per square mile of drainage area - cfs/m), that is equal to only 40% of the Aquatic Base Flow.¹ This flow does not sufficiently protect the aquatic resources in this substantial reach of river,

¹ Aquatic Base Flow is a policy used by the USFWS for establishing minimum flows in the absence of site specific data. The Aquatic Base Flow equates to the August Median Flow as determined using unregulated hydrography or on drainage area at the project site (0.5 cfs per square mile of drainage area) if unregulated hydrography is unavailable.

especially in the context of the magnitude, frequency, and duration of changes in habitat that likely occur between minimum and generation flows.

Results of the flow study will be used to determine an appropriate flow recommendation that will protect and/or enhance the aquatic resources below the Project.

Proposed Methodology

In-stream flow habitat assessments are commonly employed in developing plant operational regimes that will reduce impacts or enhance habitat conditions downstream of hydroelectric projects.

Given the length of the river reach impacted by project operations (10+ miles), we believe a study methodology that utilizes an Instream Flow Incremental Methodology (IFIM) approach is appropriate for this site. This same protocol was used during the relicensing of the Housatonic River Project (FERC No. 2576)² and has been accepted by the Commission in other licensing proceedings.³

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data along transects located in the reach of river below Cabot Station. The measurements should be taken over a range of test flows. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon habitat suitability index curves) of each test flow for target species identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the river channel downstream from the railroad bridge below the mouth of the Deerfield River. The area from the Cabot Station discharge to the railroad bridge should be modeled using 2 dimensional (2D) modeling to better characterize flows and velocities in this complex channel area.

Data collected with this study must be sufficient to perform a dual-flow analysis and habitat time series or similar approaches to assess how quality and location of habitat for target species changes over a range of flows between existing minimum flow and maximum Project generation flows.

Level of Effort and Cost

Field work for instream flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

FirstLight has not proposed an alternate study.

³ Glendale Project (FERC No. 2801) Final Bypass Reach Aquatic Habitat and Instream Flow Study in Glendale Hydroelectric Project Application for Subsequent License (FERC No. 2801), Volume 2, Appendix B, pages 7-8, October 2007.

6.3 Requested Study #3: In-stream flow habitat assessment of the Turners Falls Bypass Reach

We recommend the applicant conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species. The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species including, federally endangered shortnose sturgeon, American shad, American eel, sea lamprey, and benthic invertebrate communities.

Goals and Objectives

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources from the bypassed reach between Turners Falls Dam and the Cabot Station discharge. The objective of the study is to conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species.

Target fish species

Resource Management Goals

We seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional diadromous fishes and aquatic habitat objectives for the basin.
2. Conserve, protect, and enhance aquatic habitats for diadromous fish species that continue to be affected by the Project.
3. Ensure that project operations are not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources within the Turners Falls bypass reach, our goals are:

1. Protect, enhance, or restore diverse high quality aquatic and riparian habitats for diadromous species in the watershed and mitigate for loss or degradation of this riverine ecosystem.
2. Provide a flow regime in the bypass reach that meets the life history requirements of diadromous fish and federally listed shortnose sturgeon.
3. Avoid and/or minimize the current negative effects of project operations on shortnose sturgeon spawning and rearing within known spawning areas of the bypass reach (i.e., the Rock Dam).
4. Minimize current and potential negative project operation effects on water quality and aquatic habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

The Turners Falls Project bypasses a 2.7 mile-long section of the Connecticut River. Presently the only required spill releases from the Turners Falls dam to the bypass reach are 400 cfs from May 1 through July 15 and 120 cfs from July 16 until the river temperature reaches 7°C.

In addition to these flows provided at the Turners Falls Dam, the bypass reach receives flow from one small tributary (the Fall River, drainage area of 34.2 square miles), which enters the mainstem approximately 0.16 miles below the dam. The bypass reach also receives the discharge from Station 1, when it is generating (typically when there is flow in excess of Cabot Station's needs). This discharge enters the bypass reach approximately 0.9 miles below the dam.

Available information in the PAD does not indicate how project operations have altered downstream hydrology, habitat quantity and quality, and water quality, which may affect diadromous species and federally endangered shortnose sturgeon as well as natural processes in the Connecticut River from below the Turners Falls Dam downstream to the Cabot Station discharge. The PAD also provides no detailed description of the physical or biological characteristics of the bypass reach.

Little information exists on the adequacy of the existing bypass flow regime to protect water quality and aquatic life. However, there is existing information (not included in the PAD) relative to minimum flows necessary for shortnose sturgeon spawning and rearing at the Rock Dam spawning site (Kynard *et al.* 2012). Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period of April 27th to May 22nd (Kieffer and Kynard 2012). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 ELS captured, and the longest spawning period of 17 days) even though no spawning was detected at Rock Dam (Kieffer and Kynard 2012). Discharges in 1995 at Rock dam had dropped below 2,500 cfs by March 26th (Kieffer and Kynard 2012), which may indicate the need to have mitigated flow well in advance of spawning. Flow reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning site and not return even if flow later increased to acceptable levels. Researchers observed that rubble substrates remained dominant during fluctuating flows and cessation of spawning is likely due to velocities falling outside the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kieffer and Kynard 2012). These data represent the best available scientific information and indicate that current minimum flow thresholds at the Turners Falls project are not sufficiently protective of shortnose sturgeon spawning and rearing.

An empirical study is needed to provide information on the relationship between flow and habitat in the bypass reach for us to use in determining a flow recommendation.

Project Nexus

The Turners Falls Project includes a 2.7 mile-long bypass reach. The Project is currently operated with a seasonally-varying minimum bypass flow (200 cfs starting on May 1, increasing to 400 cfs when fish passage starts through to July 15, then reduced down to 120 cfs until river temperature drops below 7°C). The 400 cfs release is primarily to facilitate upstream movement of anadromous migrants to the spillway fish ladder at Turners Falls and the 120 cfs was intended

to provide protection to shortnose sturgeon by maintaining a wetted habitat of 1.5 x maximum adult body depth through connections between pools within the bypass reach. Neither of the currently required flows were based on quantitative, rigorous scientific studies.

This section of the Connecticut River contains habitat that supports spawning and rearing habitat for the federally endangered shortnose sturgeon. While the existing license does require seasonally-varying flow releases from the Turners Falls dam, the best available data indicates these flows are insufficient to protect shortnose sturgeon habitat and other aquatic resources within the bypass reach based upon observed spawning behavior at Rock Dam.

Results of the flow study will be used to determine an appropriate flow recommendation that will protect and/or enhance diadromous species and federally endangered shortnose sturgeon in the bypass reach for the duration of any new license issued by the Commission.

Proposed methodology

Bypass flow habitat assessments are commonly employed in developing flow release protocols to reduce impacts or enhance habitat conditions in reaches of river bypassed by hydroelectric projects.

Given the size of the bypass reach (2.7 miles long) and the important resources known to inhabit the reach, we believe a study methodology that uses an IFIM approach is appropriate for this site. This same protocol was used during the relicensing of the Housatonic River Project (FERC No. 2576)⁴ and the Commission has accepted this protocol in other licensing proceedings⁵.

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data within a range of discharge levels along transects located in the reach of river between the dam and the Cabot Station discharge. The measurements should be taken over a range of test flows up to 6,300 cfs or over a sufficient range of flows to model flows up to 6,300 cfs. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon HSI curves) of each test flow for target species/life stages identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the bypass reach from the area downstream of the spillway where the river channel constricts to Rawson Island upstream from the Rock Dam. The area from Rawson Island to the Cabot station discharge should be modeled using 2D modeling to better characterize flows and velocities in this complex channel area. Likewise, we recommend 2D modeling in the spillway area and mouth of the Falls River to the point where the channel constricts given this complex area with numerous potential flow discharge locations.

The flow study should incorporate the identified minimum flow and temporal parameters for shortnose sturgeon discussed in the Background and Existing Information section of this request.

⁴ Housatonic River Project License Application, Volume 4, Appendix F. Connecticut Light and Power Company, August 1999.

⁵ Glendale Project (FERC No. 2801) Final Bypass Reach Aquatic Habitat and Instream Flow Study in Glendale Hydroelectric Project Application for Subsequent License (FERC No. 2801), Volume 2, Appendix B, pages 7-8, October 2007.

Level of Effort and Cost

Field work for flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. Field work associated with this study could be done in conjunction with the below-project instream flow study request, Study #2. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects (e.g., the Glendale Project, FERC No. 2801). FirstLight has not proposed an alternate study.

6.4 Requested Study #4: Evaluate the frequency and impact of: 1) emergency water control gate discharge events; and 2) bypass flume spill events on shortnose sturgeon spawning and rearing habitat in the tailrace and downstream from Cabot Station

This evaluation should directly address the impact of sediment disturbance and excessive velocities on habitat in Cabot Station tailrace and downstream resulting from emergency water control gate discharge events and bypass spill events and effects of spill from the downstream fish bypass sluice on shortnose sturgeon spawning and incubation.

Goals and Objectives

The goal of this study is to determine appropriate scenarios for operation of the emergency water control gates and bypass flume that will be sufficiently protective of shortnose spawning and rearing below Cabot Station from excessive water velocities and exposure to abrasive sediments dislodged and transported across spawning and rearing areas. Furthermore, evaluating the potential for operation modifications to avoid or minimize rapid fluctuations in flow is also a goal of this study applicable to the operations of the emergency water control gates and bypass flume.

The objectives of the study are to: 1) determine how often the emergency water control gates are operated to discharge large quantities of water and evaluate the impact of these events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot Station and 2) understand the operation of the bypass flume that results in bypass flume spill events and evaluate the impacts of these spill events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot station. Even when bottom velocities fall within the range optimum for shortnose sturgeon spawning, rapid fluctuations may result in sediment transport having a harmful impact on developing eggs and embryos.

Specific Objectives include:

1. Field verification of site conditions during operation of the emergency water control gates for a range of spill and discharge conditions is necessary during years 2014 and 2015 if emergency water control gates will continue to be operated during shortnose sturgeon spawning and rearing (April 15th –June 22nd). Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the emergency water control gates that will avoid or minimize negative impacts to spawning and rearing habitat.
2. Field verification during bypass flume spill events under a range of spill and discharge conditions is necessary during years 2014 and 2015 if bypass flume spill events continue to

be a part of future project operations and will occur during shortnose sturgeon spawning and rearing (April 15th - June 22nd).

Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the bypass flume that will avoid or minimize negative impacts to spawning and rearing habitat.

Resource Management Goals

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above. We seek to understand current emergency water control gate bypass flume operations and associated impacts to determine potential operation scenarios that avoid or minimize negative effects on shortnose sturgeon spawning and rearing.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

The emergency water control gates are used to spill large amounts of water. In addition, Cabot Station also spills water from the bypass flume (Kieffer and Kynard 2007, Kieffer and Kynard 2012). It has been observed that these large spill events create a plume of turbid, turbulent flow, which caused some females to leave the area (Kieffer and Kynard 2007, Kieffer and Kynard 2012). Additional spill events create a scour effect on the bottom and the scoured sediments are then pushed downstream over, or deposited on spawning and rearing shoals where an entire years class of ELS may be destroyed (Kieffer and Kynard 2007, Kieffer and Kynard 2012). Information included in the PAD does not address operation of the emergency water control gates or bypass flume and impacts on shortnose sturgeon spawning and rearing.

Project Nexus

The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project. Based on best available data, the current operations of the emergency water control gates and bypass flume create flow dynamics that are not sufficiently protective of shortnose sturgeon spawning and rearing. Results of this study will be used to determine recommendations for operation of the emergency water control gates and bypass flume that will avoid or minimize sedimentation and maintain bottom velocities that are sufficiently protective of shortnose sturgeon spawning and rearing.

Proposed Methodology

River hydrology modeling is commonly employed at hydroelectric projects to assess implications of project operations on the river environment. It is assumed that the planned hydrologic modeling can incorporate emergency water control gate operations and associated impacts. Thus, an additional model would not be required for this request.

Field assessment will be needed to collect sedimentation and bottom velocity data at the emergency water control gates and fish bypass sluice discharge areas to determine which operational scenarios avoid or minimize impacts to shortnose sturgeon spawning and rearing.

Velocity gauges would be employed to collect data on bottom velocities associated with project operations at Cabot Station. Coordination of gauge placement for this request with the field measurements for the instream flow study should help minimize the number of necessary gauges. Field assessment of sedimentation may be collected using a variety of techniques. One potential method of collection of sedimentation data would be to set fine-mesh nets similar to shortnose sturgeon larval collection nets. These nets may show changes in the amount of dislodged substrate material that travels along the spawning site as a result of powerful releases at both the Cabot spillway and bypass flume.

Level of Effort and Cost

Field verification for this study request will likely be coordinated with other field work for related study requests. It is not expected that the required field work for this request will result in significant additional cost and effort beyond what is expected for field work related to the instream flow study request. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

FirstLight has not proposed an alternate study.

6.5 Requested Study #5: Impact of project operations on shad spawning, spawning habitat, and egg deposition in the Turners Falls and Northfield Mountain Project Area

Flows within the Connecticut River can change rapidly due to FirstLight's operations, as well as the operations of upstream projects. The U.S. Geological Survey has developed unimpacted flow estimates for the Connecticut River and several tributaries and it is clear that mainstem river flows differ from these estimates (Archfield, 2012). Given these changes in flow, it is unclear how these impacts affect spawning behavior and what the impacts are to eggs that have been deposited.

Goals and Objectives

A goal of this study would be to determine if project operations (under the permitted and proposed operational ranges) negatively impact American shad spawning site use, behavior and availability, spawning habitat quantity and quality, and spawning activity in the river reaches downstream from Cabot Station and in the project bypass reach of Turners Falls Dam, in the Turners Falls Dam impoundment and in relation to Northfield Mountain Pump Storage operations. The study would also determine the areal extent and quality of identified spawning areas, and spawning activity in terms of egg deposition in those areas.

The following objectives will address this request:

1. Determine areas utilized by American shad for spawning by conducting night-time visual observation of spawning activity, identify and define areas geospatially, and obtain data on physical habitat conditions affected by project operations (e.g., water depth, velocity, discharge, substrate, exposure and inundation of habitats).
2. Determine project operation effects on observed spawning activity, under a range of permitted or proposed project operation conditions.

3. Quantify effects (e.g., water velocity, depths, inundation, exposure of habitats) of project operation on identified spawning areas for a range of conditions, over the complete period of spawning activity.
4. Quantify spawning activity as measured by night-time spawning/splash surveys and egg collection in areas of spawning activity, and downstream of these areas, to further determine project operation effects (location extent of exposure from changing water levels and flows and on associated habitats from project operations).
5. If it is determined that Project operations adversely affect the spawning activity of American shad and impact spawning area habitat, identify operational regimes that will reduce and minimize impacts spawning habitat and spawning success, within the project area.

This study will require two years of field data to capture inter-annual variability to river discharge and water temperatures and to allow for evaluation of alternative flow regimes if year one studies determine that the present peaking regime negatively affects spawning.

Resource Management Goals

The CRASC developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.

The ASMFC, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the objective maximizing the number of juvenile recruits emigrating from freshwater stock complexes. The plan further recommends:

1. To mitigate hydrological changes from dams, consider operational changes such as turbine venting, aerating reservoirs upstream of hydroelectric plants, aerating flows downstream, and adjusting in-stream flows.
2. Natural river discharge should be taken into account when instream flow alterations are being made to a river (flow regulation) because river flow plays an important role in the migration of diadromous fish.
3. Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account instream flow needs for American shad migration, spawning, and nursery use, and minimize deviation from natural flow regimes.
4. When considering options for restoring alosine habitat, include study of impacts and possible alteration of dam-related operations to enhance river habitat.

We seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. Our goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.

2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Minimize current and potential negative project operation effects on American shad spawning and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream to the Turners Falls Dam. A number of improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad population, and numbers of shad passing Turners Falls and Vernon Dam have not met CRASC management plan objectives. Population number and passage numbers past Holyoke have declined substantially from those totals in recent years, with average Holyoke passage numbers over the last 10 years of 211,850. Since approximately half the population of shad returning to the river passed upstream of Holyoke, recent returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management goals for the Connecticut River.

American shad broadcast spawn in congregations over shallow flats and rocky or sandy substrates (Davis et al, 1970, Mansueti and Kolb 1953), at depths less than 10 feet and often far shallower with spawning fish swimming vigorously near the surface in a closely packed circle (Marcy 1972, Mackenzie et al 1985). Fertilized eggs drift downstream until hatching (Mackenzie et al 1985).

American shad are known to spawn downstream from the Turners Falls Project. Layzer (1974) identified 6 spawning sites from an area below the mouth of the Deerfield River (river mile 191.9) to river mile 161.7 below the Mill River in Hatfield, MA. Kuzmeskus (1977) verified 16 different spawning sites ranging from downstream of the Cabot tailrace to just upstream of the Holyoke dam (river mile 87.1). The only parameter that all spawning sites had in common was current (Kuzmeskus 1977). We are not aware of any more recent studies that document whether these 16 sites are still viable spawning locations for shad. We are not aware of any studies that have determined American shad spawning habitat or spawning sites upstream of Vernon Dam to Bellows Fall Dam (historic extent of upstream range).

FirstLight Power conducted studies in the late spring and summer of 2012, examined habitat conditions downstream of the Turners Falls Dam. The study documented that in low flow conditions. Cabot Station project operations produced fluctuations in water level elevations that can range over 4 feet in magnitude (daily operation) at the USGS Montague Gage Station, to lower values of 2 to 3 feet at the Route 116 Bridge, Sunderland, MA (PAD). Similar short-term,

limited monitoring in the upper Turners Falls Dam impoundment identified water level changes due to project operations that cyclically varied several feet on a sub-daily frequency.

Project Nexus

American shad are known to spawn at five locations downstream from the Turners Falls Project from an area below the mouth of the Deerfield River (river mile 191.9) and ten other locations downstream to river mile 161.7 below the Mill River in Hatfield (Layzer 1974, Kuzmeskus 1977).

Shad spawning is likely influenced by river flow, which fluctuates greatly due to the project's peaking mode of operation. These fluctuations may impact shad spawning activity by altering current velocities and water depth at the spawning sites. Effects on spawning behavior could include suspension of spawning activity, poor fertilization, flushing of eggs into unsuitable habitat due to higher peaking discharges, eggs dropping out into unsuitable substrate and being covered by sediment deposition and/or eggs becoming stranded on dewatered shoal areas as peak flows subside.

While a number of shad spawning and egg deposition studies were conducted in the 1970s, that research was aimed at assessing the potential impact of developing a nuclear power station in the Montague Plains section of the Connecticut River. We are not aware of any studies being conducted specifically designed to determine if a relationship between spawning behavior, habitat use, and egg deposition and project operations effects of the Turners Falls, Northfield Mountain Pump Storage and Vernon projects and downstream of Bellows Falls Dam.

We are concerned that peaking operations may be altering spawning behavior and contributing to the failure of the Connecticut River shad population to meet management targets.

Proposed Methodology

The first year of study should examine known spawning areas downstream of the Turners Falls Dam project, to determine operation effects on shad spawning behavior, activity, and success. In areas upstream of Turners Falls Dam the study should identify areas used for spawning by American shad. In the second year, should results from year one determine project operations affected spawning activity, access to habitat, or success, downstream of Turners Falls Dam, then an identical more detailed assessment (identified objectives) should be conducted in spawning areas upstream of Turners Falls Dam. Measures to reduce or eliminate any documented project operation impacts should be explored and evaluated in year two, downstream of Turners Falls Dam.

The impacts to spawning behavior would best be studied by night-time observations of actual in-river spawning behavior (Ross *et al.* 1993). Project discharge increases or decreases during actual observed spawning activity will provide empirical evidence of change in behaviors. We recommend observational methodology following the protocol specified in Layzer (1974) and/or as described in Ross *et al.* (1993). The analysis should use the observational field data in conjunction with operational data from the projects (station generation and spill on a sub-hourly basis). To assess the impacts of changes in generation flows, the study should include scheduled changes in project operation to ensure that routine generation changes that occur during the nighttime spawning period affect downstream spawning habitats selected for study while shad are spawning. Stier and Crance (1985) provide optimal water velocities during spawning to range between 1 to 3 ft/sec.

In areas used for spawning, the characteristics of those areas (e.g., location, depth, flow, substrate) should be recorded. The effect of project operations (discharge, water velocity, inundation and exposure) should be assessed. Drift nets should be used to collect eggs to quantify egg production before and after flow changes at the spawning site.

In the reaches above the Turners Falls dam, night time observations of splashing associated with shad spawning should be done in each reach as sufficient numbers of shad are passed above each dam. Observations should be done regularly until the end of the spawning season. The use of radio-tagged adult shad from Requested Study #7 would aid in this effort. An estimate of the total area used for spawning and an index of spawning activity should be recorded for each site.

Level of Effort and Cost

FirstLight did not propose any studies to meet this need. Estimated cost for the study is expected to be low to moderate for FirstLight, with the majority of costs associated with fieldwork labor.

FirstLight has not proposed an alternate study.

6.6 Requested Study #6: Impacts of Turners Falls canal drawdown on fish migration and populations

Currently FirstLight conducts a drawdown of the power canal for maintenance purposes. We have concerns about the time of year that this activity occurs as well as its duration based on what trust species could be present in the canal at the time of this procedure. We have received anecdotal reports of fish kills during this procedure. A well-documented study of impacts to trust species would allow us to investigate possible timing alternatives to this procedure.

Goals and Objectives

The goal of this study is to determine the impact and levels of mortality on migratory fish during the drawdown of the power canal.

Objectives of this study request include:

1. Assess the impact on juvenile American shad, adult American eel (migrants), and sea lamprey ammocetes when conducting the annual canal drawdown.
2. Evaluate measures to minimize impacts of the canal drawdown.

Resource Management Goals

The CRASC management objectives for shad includes the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Maximize outmigrant survival for juvenile and spent adult shad.

The ASFMC has the stated goal of “*Protect, enhance, and restore Atlantic coast migratory stocks and critical habitat of American shad in order to achieve levels of spawning stock biomass that are sustainable, can produce a harvestable surplus, and are robust enough to withstand unforeseen threats.*” The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the objective maximizing the number of juvenile recruits emigrating from freshwater stock complexes. The plan further recommends:

1. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate .

We seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. Our goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Minimize current and potential negative project operation effects on diadromous fishes, including juvenile shad, adult silver eels, and sea lamprey ammocetes.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as identified in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Existing information in the PAD does not provide data on the population size or survival rates of juvenile American shad, American eels, or juvenile sea lamprey located in the power canal during the de-watering process. The power canal is dewatered in early September of each year over a one week period to perform facility maintenance, inspections, and repairs including substantial silt removal and bank repairs. Historically, the canal drawdown occurred in July, but approximately five years ago it was moved to September, where it has occurred annually since then, with the exception of 2010. The agencies were informed in a letter by FLP that the shift to September was at the request of the Independent System Operator –New England (ISO-NE) to avoid peak load months of June through August. Studies conducted by the previous operator, NUSCO, to assess downstream clupeid survival and use (1991 and 1994 studies at Cabot Station) support the contention that juvenile shad out-migration is occurring within the current drawdown time frame. There are no data to suggest that out-migration would occur earlier than 1 August, but likely does begin in the month of August ((O'Donnell & Letcher, 2008). Based on these data, CRASC altered its Fish Passage Notification Letter for Downstream Passage Operations for juvenile shad and herring after the 2010 migration season to require the Cabot Station downstream bypass to operate August 15 and to August 1.

It is unknown, whether the power canal may, through a potential mechanism of delay, cause out-migrating juvenile shad to accumulate in the canal. This information gap leads to concerns that migrant numbers may be elevated beyond simple extrapolations of surface area comparison in the canal to main stem habitat. The existing near-surface downstream bypass structure at the Cabot Station is designed to operate within a depth of 6 feet of the surface, with the maximum depth of a 60 feet noted in the PAD for this area in the Cabot Station forebay. As a result, the downstream bypass only operates effectively for a short period during the drawdown period (timing of this is unknown). The only points of egress, once the bypass becomes unavailable are

through the turbines at Cabot as well as at Station 1, and eventually at the Keith Street gate. It is unknown what the survival rates are for these passage routes, what proportion of fish are using each route, what number may become stranded and their survival rates, and how many fish are subjected to this situation. The related Study Requests #8 and 10 on Downstream Juvenile Shad Outmigration and American Eel Outmigration, respectively, outline research that would answer some of these questions.

There is also a paucity of information relative to the disposition of fish moving downstream in the impoundment during the canal drawdown. Upon the Turners Falls gatehouse closing its gates, all inflow passes over the dam. Survival rates for out migrating juvenile American shad and adult American eel moving past the project during the period of spill are not known.

Lastly, there exists an information gap regarding the fate of juvenile sea-lamprey (known as ammocetes) that reside in the soft substrate materials located in much of the lower or downstream end of the canal (personal communication, Boyd Kynard, BK Riverfish LLC). In previous drawdowns, thousands to tens of thousands of dessicated ammocetes have been observed (Matt O'Donnell, USGS, personal communication). However, the distribution and abundance of ammocetes in the canal as well as survival rates for ammocetes during the drawdown period has not been quantitatively studied but anecdotally noted and observed by agency personnel making observations during the drawdown.

Project Nexus

Previous studies at Cabot Station have documented that juvenile American shad and American eel migrate through the project area during the canal drawdown period. During normal operations, downstream migrants are able to use the Cabot bypass facility; however, as the canal water level is drawn down, the bypass is no longer available, and the only routes of egress are through the turbines at Cabot Station and Station 1, unless the Cabot Station spill gates are utilized (have a canal depth limitation approximately 16 feet). Turbine entrainment at hydropower projects has been shown to cause injury and mortality to fishes.

The canal drawdown used to be conducted in July. While ISO-NE requested that FirstLight conduct the drawdown outside of the June through August period, FirstLight chose to move it to a period of time when diadromous fishes are known to be moving through the project area.

Once the canal has been drawn down, isolated shallow pools are left standing until the canal is refilled. During this days-long period, aquatic invertebrates and lamprey ammocetes are prone to desiccation and predation.

Proposed Methodology

The methods presented here are consistent with Requested Studies #8 and #10, addressing downstream juvenile American shad passage and downstream American eel passage, with an emphasis on addressing survival and movement immediately prior to and during the canal draw down. Hydroacoustic monitoring immediately upstream of the Turners Falls Gatehouse as well as upstream of opened dam gates for spill, will provide data on the timing, frequency and magnitude of natural wild juvenile shad movement into these areas. Juvenile shad moving into the canal can be derived and compared with similar data obtained with hydroacoustic equipment monitoring upstream of the Cabot Station intake and bypass. Radio tagged and Passive Integrated Transponder (PIT) tagged shad will be tagged, released, and monitored in the canal, for movements, timing and location including Station 1 canal and forebay. PIT tagged fish will

be detected at the Cabot Bypass Sluice. Radio tagged juvenile fish should be specifically targeted for released immediately prior to drawdown to assess survival and movement in and through the canal. Balloon tagged juveniles may be used to assess survival through turbine (Cabot and Station1) and gate routes (at dam and gates off of canal). Surveys of sea lamprey ammocetes may be conducted by a stratified sampling design based upon course substrate assignment filter. Lamprey densities surveys, using possibly backpack electrofishers, immediately after drawdown and in a subsequent later survey, could attempt to assess changes in observed densities, appropriate methods would need to be discussed. Surveys of remaining ponded water should be conducted immediately following drawdown and later to compare if densities increase, which may suggest movement to available water.

The canal drawdown mitigation assessment involves evaluating alternative drawdown protocols to minimize impacts to resident and migratory fish inhabiting the canal. Alternatives should include: (1) moving the drawdown to a time of year outside of migration seasons; (2) keeping or moving the timing of the drawdown, but utilize technologies to keep the majority of the canal wetted during the drawdown (e.g., portadams in the forebay immediately upstream of the trashracks); and (3) in combination with alternative #2, assess whether other existing infrastructure within the forebay could be used to pass fish safely out of the canal (e.g., low level outlets, deep gates, side spillway boards, etc.). The assessment should compare the merits and drawbacks of each alternative and provide an order of magnitude cost estimate for implementation.

Level of Effort and Cost

This Study Request has many elements that overlap directly with a larger scale study requests #8 and 10 for Downstream Juvenile American shad and Downstream American Eel, respectively. With equipment costs principally covered in those requests, many components of what has already been proposed will be used in this study. However this request does include some specific elements not specified in the other two larger requests, cost and effort are expected to be low to moderate. Some additional radio tags and balloon tags with additive days of field work to accurately assess impacts specific to the drawdown period will be required. Surveys for juvenile sea lamprey and will take several days during the drawdown period as well.

The canal drawdown mitigation assessment should require a low to moderate level of effort and cost. One staff person would evaluate alternative drawdown protocols. This should take less than one week to complete.

FirstLight has not proposed an alternate study.

6.7 Requested Study #7: Telemetry study of upstream and downstream migrating American shad to assess passage routes, effectiveness, delays, and survival

The tracking of migratory fish provides valuable information that fishery biologists use to better manage the species. Telemetry studies have been used for many years and the analyses conducted from these studies have been used to improve upstream and downstream passage conditions. Given the complexities in flow conditions and project operations that occur at the FirstLight projects and at projects further upstream in the watershed, the tracking of fish via telemetry studies is a very important requested study for us.

Goals and Objectives

The goals of this study are to assess behavior, approach routes, passage success, survival, and delay by adult American shad as they encounter the projects during both upstream and downstream migrations, under permitted project operations conditions, proposed operational conditions, and study treatment operational conditions at FirstLight Power's Turners Falls and Northfield Mountain Pumped Storage projects. There are multiple ladders and issues related to both upstream and downstream passage success at the projects. Some of these issues at the Turners Falls Project are similar to and/or pertain directly to the Northfield Mountain. Therefore, it is reasonable to address passage issues at all projects in a similar manner. The following objectives shall be addressed in these studies:

1. Assessment of any migration delays resulting from the presence of the dam and peaking flow operations of the Turners Falls Project.
2. Determine route selection and behavior of upstream migrating shad at the Turners Falls Project under various spill flow levels (e.g., movement to the dam, attraction to Cabot Station, attraction to Station 1 discharge, movement between locations, delay, timing, etc.). A plan and schedule for dam spill flow releases will need to be developed that provides sufficient periods of spill flow conditions, and various generating levels from Turners #1 Station coupled with Cabot Station generation flows (e.g., treatments will require multiple days of consistent discharge). Evaluated spill flows should include flows between 2,500 – 6,300 cfs, which relate to bypass flows identified as providing spawning opportunities for shortnose sturgeon in the lower bypass reach at the Rock Dam. (Kieffer and Kynard 2012). Sturgeon spawning and upstream shad passage occur concurrently;
3. Assess near field, attraction to and entrance efficiency of the Spillway Fishway by shad reaching the dam spillway, under a range of spill conditions;
4. Evaluate the internal efficiency of the Turners Falls Spillway Fishway;
5. Continue data collection of Cabot Station Fishway and Gatehouse Fishway efficiency, to include rates of approach to fishway entrances, entry into fishways, and passage through them, under different operational conditions that occur in these areas;
6. Assess upstream migration from Turners Falls to the Vernon Dam in relation to Northfield Mountain's pumping and generating operations and Vernon Project peaking generation operations. Typical existing and proposed project operation alterations should be evaluated;
7. Assess impacts of Northfield Mountain operations on up- and downstream adult shad migration, including delays, entrainment, and behavioral changes and migration direction shifts under existing and proposed project operations;
8. Determine downstream passage route selection, timing/delay, and survival under varied project operational flows into the power canal and spill flows at Turners Falls Dam;
9. Determine downstream passage route selection, timing/delay in the canal, Cabot Station fish bypass facility effectiveness, and survival of Cabot-bypassed adult shad that enter the Turners Falls Canal system;
10. Compare rates and or measures of delay, movement and survival etc., among project areas or routes utilized (e.g., spill at dam vs. power canal) under the range of permitted and proposed conditions; and

11. Use available data sets and further analyze raw data (e.g., 2003- 2012 Conte Lab Studies) where possible to address these questions and inform power analyses and experimental design.

Information to address all of these questions would rely on the tagging of upstream migrating adult shad at Holyoke Dam and releasing them to migrate naturally from Holyoke through the Turners Falls and Vernon projects and back downstream after spawning. Additional tagged individuals would likely need to be released farther upstream (Turners Falls Canal, and upstream of Turners Falls Dam) to ensure that enough tagged individuals encounter project dams on both upstream and downstream migrations, that these individuals are exposed to a sufficient range of turbine and operational conditions to test for project effects, and to provide adequate sample sizes for statistically valid data analyses to address the many objectives listed. This study will require two years of field data collection to attempt to account for inter-annual variability in river discharge and water temperatures.

In addition to collection and analysis of new telemetry data, substantial data has already been collected at Turners Falls from multiple years of passage assessments conducted for FirstLight by U.S. Geological Survey's Conte Anadromous Fish Research Center (Conte Lab) researchers. There are also data from the 2011 and 2012 full river study conducted by the Conte Lab that address Turners Falls and Northfield Mountain migration and passage questions that have not yet been analyzed. These data include several million records each year from more than 30 radio telemetry receivers deployed between Middletown, CT and Vernon Dam. This data will provide substantial information free from the field data collection costs and therefore should be analyzed as part of this study. This data analysis should be completed in 2013 to help inform the design of subsequent field studies.

The poor passage efficiency of the Cabot Fishway, the first and most used ladder encountered by shad arriving at the Turners Falls Project, and at the entrance to the Gatehouse Fishway, which all Cabot Fishway-passed fish must use, has resulted in very poor overall shad passage efficiency at the project. An alternative to passing fish at the Cabot Station is to install a fish lift at the dam that would put fish directly into the Turners Falls pool, thereby eliminating problems with the Cabot Fishway, and the Gatehouse Fishway entrance and the variable passage efficiency of the Gatehouse Fishway. For this to be effective, attraction of shad to the Cabot Station discharge and associated delays would need to be overcome. It is possible that spillway flow releases coupled with behavioral measures at Cabot Station that dissuade shad from that tailrace could achieve this end. To assess the possibilities, we recommend the following study be included within the scope of this study request:

1. A literature search and desk-top assessment of the possible behavioral measures that could be effective in getting shad to pass Cabot Station tailrace and continue upstream to the dam.
2. Based on results of the desk-top assessment, possible evaluation of behavioral measures that are likely to be effective.
3. Field evaluation of the effect of different levels of spill at the dam that would induce fish to move past the Cabot Station into the bypass reach and up to the dam (as noted in objectives).

Besides passage success and delays at passage facilities, these studies would assess the impacts of project operations on migration passage delay, route, timing, injury, mortality, and passage

structure attraction, retention, and success. Of particular interest will be fish behavior during periods when flow releases from the project increase from the required minimum flows to peak generation flows and when flows subside from peak generation flows to minimum flows and the operation of NMPS in pumping and generation modes.

Resource Management Goals

The CRASC developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

The ASMFC, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the objective of maximizing the number of juvenile recruits emigrating from freshwater stock complexes. Further, the ASMFC provided the following recommendations for upstream and downstream passage:

1. American shad must be able to locate, enter, and pass the passage facility with little effort and without stress.
2. Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
3. Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.
4. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the least delay and best survival rate.

Based on the CRASC plan, we seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project including:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Minimize current and potential negative project operation effects such as migration delays, false attraction, turbine entrainment, survival of project passage routes, and trashrack impingement that could hinder management goals and objectives.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates described in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Passage of adult shad at the Turners Falls project has been the subject of intense study by the Conte Lab since before 1999. These studies have clearly demonstrated that passage through the existing ladder at Cabot is poor (<10% in many years). Passage through the Gatehouse Fishway is better, but still rarely exceeds 80%, despite the short length of this ladder. In addition to poor passage for fish entering the ladders, shad that ascend the Cabot Fishway experience extensive delays before entry into the Gatehouse Fishway. Shad that ascend the Spillway Fishway frequently fall back into the canal and are also subject to these upstream delays. A new entrance to the Gatehouse Fishway installed in 2007 led to dramatic improvements in passage out of the canal (from 5% to over 50% in 2011), but passage still falls well short of management goals. In addition, shad spend considerable time (up to several weeks) attempting to pass. These delays likely influence spawning success and survival. Adult shad, unable to pass Gatehouse, experience similar delays in downstream passage, even after they have stopped trying to pass Gatehouse. Without spill, all outmigrating shad that have passed Gatehouse must enter the canal at the Gatehouse and may be subject to delays exiting the canal.

During the course of these studies a very large dataset has been compiled that could yield useful information for further improving passage of shad out of the canal in both the upstream and downstream directions. A unique feature of these data is a 2-dimensional array covering the canal just downstream of Gatehouse, documenting fine scale movements and occupancy of this zone. These data should be combined with computational fluid dynamics (CFD) and real-time hydraulic data to determine how canal hydraulics influence the ability of shad to locate and enter the ladder, and to identify modifications that are likely to lead to improvements in approach and entry rates. A separate CFD modeling study is requested that includes modeling of the Gatehouse Fishway entrance at the head of the power canal.

In addition, whole-river shad telemetry studies performed in 2011 and 2012 will likely provide useful information and should be analyzed. These data should allow quantification of delay below Turners Falls, and could help guide studies requested above. Preliminary analyses of data through 2011 have been made available to FirstLight and the resource agencies (Castro-Santos and Haro 2005; Castro-Santos and Haro 2010).

The whole-river studies have also shown that, at least in 2011, most shad that pass Turners Falls rapidly progress upstream to Vernon Dam where, extensive delays also occur. Data from the 2012 study were not available at this time, but Dr. Castro-Santos stated similar patterns were noted in the data between the years on the topic of upstream delay (personal communication, Dr. Castro-Santos, USGS). Similarly, concerns relative to the downstream passage of spent shad also remain relative to delays, with existing unpublished USGS telemetry data sets suggesting this is an issue within the Turners Falls canal.

Since the first year of operation of the Turners Falls upstream fishways (1980), the percent passage of American shad annually passed upstream of Turners Falls Dam compared to the number passed at the Holyoke Fish Lift has averaged 3.6% (1980-2012 data). The highest values for this metric has not exceed 11% and are well below the noted CRASC Management Plan target range for this objective noted earlier as 40-60% on a five year running average.

Project Nexus

Existing project operations (peaking power generation) and limited bypass flows have a direct impact on instream flow and zones of passage (migration corridors). Project flow releases affect passage route selection, entry into ladders, and create delays to upstream migration. Inefficient downstream bypasses can result in migration delays and increased turbine passage. Mortality of adult shad passing through these turbines is expected to be high (Bell and Kynard 1985), additional stresses associated with passage and delay may cause mortality as shad are unable to return to salt water in a timely manner. The Project's upstream and downstream passage facilities need to be designed and operated to provide timely and effective upstream and downstream fish passage to meet restoration goals of passage to upstream habitat and maximize post-spawn survival. These factors are all critically important to the success of restoration efforts.

Proposed Methodology

Use of radio telemetry and passive PIT tags are widely accepted as the best method to assess fish migratory behavior and passage success. Fishery biologists have used them extensively to assess migration and passage issues at Turners Falls as well as other Connecticut River projects. These studies include one conducted in 2011 and 2012 by the USFWS and U.S. Geological Survey's Conte Anadromous Fish Research Center, which has provided substantial information related to some of the issues identified here. The requested study will build and expand on the information collected over the past two years.

The study design must specify sample sizes, tag configurations and receiver configurations to ensure that rates of entry and exit to the tailraces, ladders, downstream bypasses, and the bypassed reach can be calculated with sufficient precision to determine effectiveness of flow. For project assessments at Turners Falls (e.g., Cabot, Spillway and Gatehouse Fishway attraction and entry, route selection, operational effects), double tagged (radio and PIT) shad will be required for release from Holyoke Dam. Additional shad must be released directly into the Turners Falls Canal to support assessment of the various operational and structural conditions in effect, to be modified in this period, and proposed conditions within the Turners Falls power canal relative to entrances to the Gatehouse Fishway. A related request on CFD modeling (Requested Study #12) in the Cabot Station tailrace, the upper power canal near Gatehouse, and in the area around the entrance of the Spillway Fishway will address related project operational effects that will also address identified objectives in this telemetry request. Shad captured at Holyoke and tagged and released upstream of Turners Falls Dam, or tagged out of Gatehouse Fishway, would help to ensure an adequate sample size for evaluations in the vicinity of NMPS and to the Vernon Dam and the ability to address identified study objectives in those project areas. The required number of tagged fish to address study objectives may be adjusted accordingly from area to area depending on target numbers (i.e., best information on resultant viable tagged fish and power analyses to detect effects) to account for typical passage rates, survival rates, and handling effects as examples.

Existing information on captured, handled, tagged fish performance (e.g., percent that drop back, unsuitable for tracking) and factors such as timing of tagging and potentially transport, must all be carefully considered to ensure an adequate sample size of healthy (e.g., viable to characterize behavior, survival, etc.) tagged fish is available to address the many questions identified in this request (as supported by a statistical power analysis). Additionally, ensuring adequate

downstream adult fish sample sizes (to address project effect questions above) requires close consideration as expected losses of healthy tagged fish during upstream passage, natural mortality rates, and tagging related effects, are expected to reduce sample sizes on downstream passage objectives/questions as the season progresses. The use of single PIT tagged fish can help improve sample sizes, but will be of limited use to answer some of the passage questions we have identified.

Due to environmental variability, two years of study work will be necessary. A large array of stationary monitoring stations (radio and PIT) will be needed to address the issues identified among the project areas. A sufficient level of radio receiver and PIT reader coverage will be required, to provide an appropriate level of resolution, for data analyses, to answer these questions on project operational effects. The study will provide information on a variety of structural and operational aspects of fish migration, relative to route selection, timing, survival, and up and downstream passage attraction, retention, delay, efficiency, survival as some examples at three projects (Turners Falls, NMPS, and Vernon). The use of video monitoring may also be utilized for specific study areas such as the Spillway Fishway, to provide additional information on shad entrance activity, with the understanding of some data limitations associated with this approach (fish identification, water visibility).

In addition to the tagging studies, use of video monitoring of the Spillway Fishway would provide additional overall data on Spillway Fishway efficiency as all shad attempting to pass could be monitored versus just those shad that have been tagged.

Level of Effort and Cost

The requested study is extensive and will require a substantial effort and cost to capture, PIT tag and radio tag a sufficient number of shad at Holyoke to release at upstream locations. We are not aware of any other study technique that would provide project specific fish behavior and migration information to adequately assess existing project operations and provide insight in possible alternative operations and measures needed to address observed negative impacts to fish migration success. Cost for the entire multi-project tagging, tracking and data analysis are expected to be very high based on past Turners Falls' studies and the 2011 and 2012 shad telemetry studies. Video monitoring of the Spillway Fishway would add a modest cost to this study.

Since tagged shad will move throughout the larger five project area, to varying degrees, there will be expected cost savings (e.g., radio tags) to both owner/operators, provided cooperation in study planning and implementation occurs.

FirstLight has not proposed an alternate study.

6.8 Requested Study #8: Impact of project operations on downstream migration of juvenile American shad

Juvenile shad that start their migration towards the sea can be as small as two inches. The degree to which turbines inflict injury or mortality on these fish at Cabot Station and Station One is not well understood. Ensuring that these trust species have safe, timely and effective passage is a condition of the Federal Power Act.

Goals and Objectives

The goal of this study request is to determine if project operations affect juvenile American shad outmigration survival, recruitment, and production. The objectives of this request include:

1. Assess project operations effects of NMPS and Turners Falls Dam on the timing, orientation, routes, migration rates, and survival of juvenile shad;
2. Determine the proportion of juvenile shad that select the Gatehouse into the power canal versus the dam spill gates as a downstream passage route, under varied operational conditions, including a range of spill conditions up to full spill;
3. Determine if there are any delays with downstream movement related to either spill via dam gates or through the Gatehouse and within the impoundment due to operations (i.e., NMPS pumping and generation);
4. Determine survival rates for juvenile spilled over/through dam gates, under varied operation conditions, including up to full spill during the annual fall power canal outage period;
5. Determine the juvenile downstream passage timing and route selection in the power canal to: Station 1; Cabot Station; and the Cabot Station log sluice bypass, and assess delays associated with each of these locations and with project operations (e.g., stockpiling in the canal);
6. Based upon year 1 study results on route selection, determine the survival rate for juvenile shad entrained into Station 1; and
7. Determine the survival rates for juvenile shad entrained into Cabot Station units;
8. If it is determined that Project operations adversely affecting juvenile shad survival, migration timing, or other deleterious population effects, identify operational solutions or other passage measures that will reduce and minimize these impacts within the project area.

This study will require two years of field data to capture inter-annual variability of river discharge, water temperatures, and variability in the timing and abundance of juvenile production and their outmigration timing, which may relate to spring, summer, and fall conditions. This study will complement the NMPS Fish Entrainment Study Request which includes assessment of impacts to juvenile shad.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Maximize outmigrant survival for juvenile and spent adult shad.

The ASMFC *Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management)*, approved in 2010 includes an objective to maximize the number of juvenile recruits emigrating from freshwater stock complexes. Further, the ASMFC recommends enhancing survival at dams during emigration, evaluate survival of post spawning

and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

We seek to accomplish a number of resource goals and objectives through the relicensing process for the Project including:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Minimize current and potential negative project operation effects on juvenile American shad survival, production, and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates as described in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Since the construction of the Turners Falls Dam upstream fishways in 1980, American shad have had access to spawning and rearing habitat upstream of Turners Dam. A number of modifications to the Turners Falls fishways have occurred since that time, with the numbers of adult shad passed at Gatehouse Fishway (into Turners Falls Dam impoundment) reaching as much 60,089 in 1992 when a record 721,764 shad passed upstream of Holyoke Dam. However, since 1980 an average of only 3.6 % of the adult shad passed upstream of Holyoke Dam subsequently have passed upstream of Turners Falls Dam, and this value has never exceeded 11%. This value is well below the CRASC 1992 Shad Plan objective of 40-60% passage from the previous dam. In addition, population number and passage numbers past Holyoke have declined substantially, with the average Holyoke passage number over the last 10 years being 211,850. Because historic data suggests that approximately half the returning adult shad to the Connecticut River pass the Holyoke Dam, recent adult returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management restoration goals for the Connecticut River, which extends to the Bellows Falls Dam. In 1990, FirstLight's predecessor, NUSCO, CRASC and its member agencies, signed a Memorandum of Agreement on downstream fish passage to address both juvenile and adults at the Turners Falls Project and Northfield Mountain Pumped Storage Project.

American shad broadcast spawn with the highest spawning activity occurring in runs and lowest activity in pools and riffle/pools (Ross *et al.* 1993). Field research by Ross *et al.* (1993) in the Delaware River further noted that a combination of physical characteristics that seems to be avoided by spawning adults is slow current and greater depth. American shad year-class strength has been shown to depend on parent stock size and environmental conditions during the larval life stages (Creeco and Savoy 1984). Delays in juvenile American shad outmigration may affect survival rates in the transition to the marine environment (Zydlewski *et al.* 2003). One published

study on the Connecticut River identified that juvenile shad outmigration began when declining autumn temperatures reached 19C and peaked at 16C (O’Leary and Kynard 1986).

Juvenile American shad production has been monitored upstream of the Vernon Dam and immediately downstream of that dam by Vermont Yankee Nuclear as part of an annual monitoring program using both boat electrofishing (since 1991) and beach seining (since 2000). Sampling of juvenile shad was also conducted by a contractor hired by Northeast Utilities in the Turners Falls impoundment in 1992. O’Donnell and Letcher (2008) examined juvenile shad early life history and migration upstream and downstream of Turners Falls Dam. Their study results led to the decision by the agencies to require earlier operation of downstream fishways to protect early season juvenile shad out-migrants (1 September prior to 2010, 15 August in 2010, and since 2011, 1 August).

Downstream juvenile clupeid passage studies at Turners Falls were conducted in the fall of 1991 which included the objectives of determining the percentage of juvenile shad and herring that pass via the bypass log sluice or that were entrained in the Cabot Station turbines and related data (e.g., catch rates) were compared. The 1991 Downstream Clupeid Study did not assess survival rates for juveniles for either of these passage routes. The 1991 study report documented a higher rate entrainment into the project turbines (23.0 fish per minute) versus through the bypass sluice (11.6 fish per minute). It was concluded that only an estimated 54% (average bypass rate, weighted by estimated number bypassed) of the juvenile American shad approaching Cabot Station were bypassed via the log sluice. The range of the percent bypassed varied widely by date, between nearly 0 and 83%, with ‘no clear explanation as to why.’ The report did not identify the percentage entrained into the turbines but it can be reasoned to be substantial based on the data presented in the report or assumed as the remaining balance (46%), as there were no spill events reported during this study, and therefore nowhere else for them to pass. It was further noted that entrainment rates for juveniles were consistently greatest for units 1 and 6 (powerhouse ends), not uniform across all units. Although no concurrent bypass sampling occurred during the first entrainment sampling events, it was noted that “entrainment rates were relatively high during the end of September.” Additional modifications have occurred over time without quantitative evaluation to improve downstream passage attraction and use to the bypass sluice, including lighting systems.

The 1994 Downstream Juvenile Shad Study report assessed juvenile shad survival from passage via the log sluice, reported to be 98%, based on tagged and recaptured fish (held for up to 48 hours). Scale loss (<20%) (22 of treatment fish) compared with scale loss of >20% (5 of treatment fish) was examined and determined to occur in an overall total of 10% of study fish (adjusted by control fish data). Given these impacts to juvenile shad that were found almost 20 years ago, FERC should request the licensee to determine what level of impact current operations are having on downstream migrating juvenile shad.

Project Nexus

Adult American shad passed upstream of Turners Falls Dam use upstream spawning habitat. Juvenile American shad production occurs in these habitats upstream of Turners Falls Dam on an annual basis. Juvenile American shad require safe and timely downstream passage measures to have the opportunity to contribute to the fishery agencies’ target restoration population size.

We are not aware of any studies being conducted specifically designed to determine:

- When spill gates are open at the Turners Falls Dam?
- What proportion of juvenile outmigrant shad take that route of passage?
- What is the rate of survival under a range of spill and gate configurations?
- What is the timing, duration, and magnitude of juvenile shad outmigrants in summer and fall to the Turners Falls Dam and Gatehouse?
- Are there delays in migration/movement at the dam, Gatehouse, Cabot Station, or Station 1?
- For juveniles that enter the power canal, what proportion subsequently enter the Station 1 power canal?
- As there are no downstream passage facilities at Station #1, and trash rack spacing is 2.6 inches, what is the survival rate of juvenile shad entrained at Station #1?
- What is the rate of movement through the Turners Power Canal, relative to r delay to outmigrant juvenile shad and the potential accumulation of juveniles (e.g., prior to the canal drawdown in September)?
- What proportion of juvenile shad use the downstream sluice bypass versus the Cabot Station turbines under varied operational conditions given that project operations may change (PAD notes possible increase in turbine capacity at Cabot)?
- Based upon earlier facility studies (1991 Downstream Clupeid) a large proportion and number of juvenile shad are entrained into Cabot Station turbines. What are the associated impacts in terms of short-term and longer term survival and injury.

We are concerned that project operations may impact juvenile shad outmigration survival and be contributing to the failure of the Connecticut River shad population to meet management targets. In the PAD, proposed modification include; Station 1 may be upgraded with new turbines, Station 1 may be closed, and/or the turbine capacity at Cabot may be increased. It is unclear how these scenarios will affect the questions identified in this request.

Proposed Methodology

The impact to juvenile shad outmigrants by project operations would be best studied by a combination of approaches including hydroacoustic, radio telemetry, and turbine balloon tags. Project discharge over a full range of existing and, to the extent possible, potential future operational conditions at Station 1 and Cabot, at the dam (likely increased bypass reach flows in new license) and in relation to the Gatehouse, should be examined relative to timing, duration, and magnitude of juvenile shad migration to and through these areas, with hydroacoustic equipment for natural/wild fish evaluation. In addition, study fish should be collected and tagged (PIT, radio, other mark, balloon) to also empirically determine rates of survival for fish passed over or through the dam's gates, under varied operations, including up to full spill condition that occurs annually in fall with canal outage period. The understanding of the timing, magnitude, duration of the wild fish outmigration will help inform the design, data/results, and assessment of tagged study fish. The release of tagged or marked fish (radio, PIT) upstream of the Gatehouse induction into the power canal, will provide data on concerns of delay and route selection to Station 1, Cabot Station downstream bypass, Cabot Station spill gates, and Cabot Station turbines. Additional hydroacoustic assessment at Cabot Station forebay will provide information on wild/natural juvenile fish timing, magnitude, and duration to and through this area. Based

upon Year 1 study findings relative to the frequency, magnitude, timing of juvenile American shad that end up in the forebay of Station 1, the determination of whether an entrainment survival study at that site is necessary will be made. Release sites for tagged fish will be determined based upon further consultation among the parties.

Radio tagged juvenile shad will be released in areas upstream of the NMPS facility at multiple release locations, to determine operation effects on migration rates, route, orientation, entrainment, and survival, over a full range of permitted and operational conditions.

Level of Effort and Cost

FirstLight does not propose any studies to meet this need. Estimated cost for the study is expected to be high, with the majority of costs associated with equipment (hydroacoustic gear, radio tags, radio receivers, and PIT readers) and related fieldwork labor.

FirstLight has not proposed an alternate study.

6.9 Requested Study #9: Upstream American eel passage assessment at Turners Falls

American eel are currently present in the mainstem Connecticut River. Upstream migrants have been found within the Turners Falls headpond as well as at the Vernon project (P-1904) as evidenced in the PAD filed by Trans Canada. The exact migratory routes that these eel take at the Turners Falls project are not currently well understood.

Goals and Objectives

The goal of this study is to determine where eel are likely to migrate within the Turners Falls project and determine what structures and flow paths they are most likely to follow.

This study has two objectives:

1. Conduct systematic surveys of eel presence/abundance at Cabot Station discharge, Station #1 discharge, canal discharges, and Turners Falls Dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective locations to place upstream eel passage facilities.
2. Collect eels with temporary trap/pass devices from areas identified from surveys as potential locations of eel concentration to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

Resource Management Goals

The goals of the ASMFC management plan for American eel (2000) include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the CRASC developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, we seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to upstream passage of American eel, our goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize project-related sources of upstream passage delay, injury, and stress in order to facilitate access to historical rearing habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates are described in Section 4 above.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

The PAD contains no information relative to areas where eels seeking to move upstream concentrate downstream of the dam, or annual numbers of eels attempting to ascend past Turners Falls Dam. While eels have been known to ascend the Cabot Station Fishway (personal communication with A. Haro, U.S. Geological Survey) its efficiency is unknown, and it is only operated during the American shad passage season (from April 1 through July 15). Eels are currently able to pass the Turners Falls Dam complex (as evidenced by documented presence of eels upstream), but the total number of eels attempting to pass Turners Falls and the proportion successfully passing the project is unknown (but suspected to be low). The downstream Holyoke Project has operated upstream eel passage facilities since 2004. Last year these facilities passed over 40,000 juvenile eels. While there is rearing habitat in between the Holyoke and Turners Falls dams, some eels will attempt to continue upstream, and passage needs to be provided so these fish can access historical habitat.

These information gaps need to be filled so resource agencies can determine the best locations to site upstream eel passage facilities and assess whether operating the existing anadromous ladders would be an effective mechanism to move juvenile eels upstream past the project.

We also note that within the past seven years, USFWS has received two petitions to list the American eel under the ESA. The first petition was received on November 18, 2004. On July 6, 2005 the USFWS issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability (CESAR). On September 29, 2011 the USFWS issued a substantial 90-day finding and initiated a 12-month status review. The USFWS is still accepting new American eel information for the ongoing status review. Although the date for completion of the USFWS 12-month finding on the latest petition is uncertain, it is likely that it will be made before any new licenses are issued for the projects.

Project Nexus

The project generates hydropower on the head created by the Turners Falls dam. This dam creates a barrier to upstream migrating eels. While some eels are able to pass dams, some are not, and the passability of a given dam depends on factors such as its height, hydraulics, presence of climbable surfaces, presence of predators, risk of exposure to heat or drying while climbing a dam, etc. The Turners Falls dam is high (35 feet above bedrock), and the majority of the dam face is dry during most of the upstream eel passage season. Design of the dam is not currently amenable to passage of eels by climbing. While flow is released to the bypass reach via a bascule gate (typically the one closest to the gatehouse), this would not facilitate eel passage, as bascule gates open outward and downward (i.e., requiring the eels to essentially swim nearly upside down to get over the gate). As mentioned earlier, the existing anadromous passage facilities are not designed to pass eels, and even if some eels are able to ascend the ladders, they may incur delays (in attraction or passage rates), be size-selective (e.g. velocity barrier for small eels presented by ~8 ft/sec flow through weirs and orifices), present a potential predation risk (predators in or near the fishways), and are not operated throughout the upstream eel passage season.

Proposed Methodology

Objective 1: Systematic Surveys

Surveys of eel presence and relative abundance should be conducted at regular intervals throughout the eel upstream migratory season (~1 May to ~15 October, or when river temperatures exceed 10 C). Surveys should consist of visual inspection and trapping in likely areas where eels may concentrate as they attempt to climb structures wetted by significant spill or leakage flow in the Turners Falls dam complex area. These locations include: Cabot Station downstream bypass outfall, Cabot Station spillway (including attraction water stilling basin), Cabot Fishway (dewatered state), USGS Conte Lab flume outfall, Number One Station outfall, various small turbine and process water outfalls from the Cabot Canal, Spillway Fishway attraction water stilling basin, and leakage points along the downstream face of Turners Falls Dam (bascule and taintor gates). Methods should include visual surveys (on foot, from a boat, or snorkeling) and trapping using small mesh (< 1/8" clear opening) baited eel pots. Visual surveys must be performed once per week, at night, preferentially during precipitation events. Trap sets

must be performed once per week, with an overnight soak time. Recorded data must include location, observation of eels (presence, absence, relative numbers, relative sizes, behaviors, time/date of observation), and survey method.

Objective 2: Trap/Pass Collections

Areas identified from Systematic Surveys as having significant number of eels present must be targeted as potential areas for permanent eel trap/passes, and must be initially assessed using temporary/portable trap passes. At a minimum (regardless of survey results), temporary trap passes must be installed at the following locations: Cabot Fishway attraction flow stilling basin (during dewatered fishway period), Number One Station outfall, and Spillway Fishway attraction flow stilling basin (during watered and dewatered fishway period), as these locations may be supplemented with additional attraction flow and have high potential for being concentration points for upstream migrant eels. Temporary trap/passes must be purpose-designed and built for each location, and operated throughout the eel upstream migratory season (~1 May to 15 October, or when river temperatures exceed 10 C). Ramp-type traps with supplementary attraction flow are preferred temporary trap/pass designs. Traps must operate daily, with catches quantified every 2-3 days. Recorded data must include location, trapping interval, absolute numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.

All collected eels from surveys should be released at their point of capture; those eels collected from trap/pass collections should be transported to and released above the dam in the Turners Falls Pool.

These methodologies are consistent with accepted practice.

Level of Effort and Cost

The level of cost and effort for the survey component of the study would be low; a minimal number of personnel may be able to conduct the weekly surveys. The trap/pass component would require low to moderate cost and effort.

In the PAD, the applicant has identified the need to assess issues related to upstream passage for American eels at the project, but indicates that it intends to rely on information from previously conducted studies and ongoing studies. We are not aware of any previously conducted or ongoing studies related to upstream eel passage.

6.10 Requested Study #10: Downstream American Eel Passage Assessment at Turners Falls and Northfield Mountain

Adult eels spend the majority of their lives in freshwater rivers. The age at which migrate out to sea and head towards their spawning grounds varies. Adult eels that embark on this migration can exceed two feet in length. Eel that pass hydro-electric projects are subjected to harsh or lethal conditions as they pass through the turbines. Currently, our understanding of the impacts and level of mortality on migrating adult eels is not well understood.

Goals and Objectives

The goal of this study is to determine the impact of two hydroelectric projects on the outmigration of silver eels in the Connecticut River. Entrainment of eels at the Northfield

Mountain Pumped Storage Station (NFMPS) removes eels from the river, prohibits a timely migration effectively extirpating them from the population. Entrainment at the conventional turbines at Station 1 and Cabot Station of the Turners Falls Project can result in mortality or injury. It is important to understand the passage routes at each project and the potential for mortality to assess alternative management options to increase survival.

The objectives of this study are:

1. Quantify the movement rates (including delays) and relative proportion of eels passing via various routes at the projects; i.e. for NFMPS, the proportion entrained into the intakes; for Turners Falls Dam, the proportion entrained into the power canal and spilled via bascule and taintor gates; for the Cabot Canal, proportion of fish passing via spillways, turbines, and the downstream bypass.
2. Evaluate instantaneous and latent mortality and injury of eels passed via the Turners Falls Dam routes, including bascule and taintor gates, spillways, turbines, and the downstream bypass.

Resource Management Goals

The goals of the ASMFC management plan for American eel (2000) include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel. Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the CRASC developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, we seek to accomplish a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to downstream passage of American eel, our goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.

2. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to our mandates described in Section 4 above.

Public Interest

The requester, NMFS, is a federal resource agency.

Existing Information

The PAD contains information on the biology, life history, and regulatory status of American eel. It also discusses 2-D and 3-D telemetry studies that were conducted at Cabot Station in 1996, 1997, 2002 and 2003. Results of those studies indicate that a significant proportion of eels entering the Cabot forebay become entrained (90% in 2002, 100% in 2003; (Brown *et al.* 2009). The PAD notes that the study done in 2003 determined that 15 of the 29 test eels were detected at the Hadley Falls Station. However, that study was not designed to assess turbine mortality.

To date, no directed studies of eel mortality at Cabot Station or eel entrainment or mortality at either Station 1 or the NFMPS facility have been conducted. Information from the requested study is needed to assess the relative and cumulative impact of project operations on outmigrating eels and develop adequate passage and protection measures to meet management goals and objectives.

Project Nexus

The Turners Falls Project operates as a peaking facility, except during periods when inflow exceeds the hydraulic capacity of Cabot Station and Station 1. Silver eels outmigrate during the mid- summer through late fall, a time of year when flows are generally near the maximum operating capacity of the stations. Therefore, the project would be expected to spill infrequently during the silver eel outmigration beyond the nominal amount required in the bypass reach.

Racks at Cabot Station, Station 1, and NFMPS facility are not designed to protect eels from entrainment. At Cabot, the racks have one-inch clear spacing on the top 11-feet, with five-inch clear spacing on the bottom 20 feet of racks. The approach velocity at the racks is approximately 2.0 feet per second at maximum hydraulic capacity. At Station 1, the racks have 2.6-inch clear spacing and an approach velocity of 1.2 feet per second. Eels can readily pass through a 2.6-inch clear space. NFMPS has 48-foot-deep trashracks with six-inch clear spacing over the intake and an approach velocity of 3.5 feet per second at full pumping capacity (15,000 cfs).

As mentioned above, previous studies conducted at Cabot Station documented eel entrainment. Cabot Station has existing downstream passage facilities designed for anadromous species, but studies have documented few eels utilizing the surface bypass (likely because Cabot has a relatively deep, wide intake area). Station 1 has no passage and protection facilities. NFMPS has a seasonally-deployed barrier net to minimize entrainment of Atlantic salmon smolts, but it is only operated from April through June 15 annually. While no studies have been conducted at Station 1 or NFMPS facility, the rack spacing is wide enough to allow for entrainment.

Proposed Methodology

In order to understand the movements of outmigrating silver eels as they relate to operations at the Northfield Mountain Pump Storage Facility, Station 1, and Cabot Station, radio telemetry technology should be utilized. Radio telemetry is an accepted technology that has been used for a number of studies associated with hydropower projects, including at the Muddy Run Project (FERC No. 2355).

Studies should be designed to investigate route selection (i.e., entrainment vs. spill) independently from estimation of mortality/injury, because these metrics require different telemetric methodologies. Studies will also likely benefit from data from several seasons (especially route selection studies, which may be more significantly affected by environmental conditions during a given season than mortality/injury studies). It is also envisioned that results from route selection studies can guide design of turbine mortality studies. Therefore, it is proposed, at a minimum, that route selection studies be conducted in multiple years, but mortality/injury studies may be conducted after the first year of route selection studies have been completed.

Objective 1: Route Selection

This study will involve systematic releases of radio-tagged silver phase eels at strategic points above areas of interest, to assess general routes of passage (i.e., via spill, bypass, or turbines). Active downstream migrants should be collected within-basin if possible (i. e., Cabot or Holyoke bypass samplers), but fish sourced from out of basin may be acceptable to meet sample size demands. Experimental fish must meet morphometric (e.g. eye diameter relative to body size) criteria to ensure they are migrant silver phase. Collections should be made within the migratory season (late Aug to mid Oct), and eels should be tagged and released within 7 days of collection.

We request consultation with the resource agencies to determine the number of tagged fish that would be necessary and where receivers should be placed for this requested study in order to better understand route selection at NMPS and throughout the Turners Falls project. The route selection portion of this study should occur in both study years.

Objective 2: Spill, Bypass, and Turbine Mortality/Injury Studies

Spill, bypass, and turbine mortality will be assessed using a radio-telemetric balloon tag method. As with the route selection study, we request consultation with the resource agencies in order to determine the number of fish required for this study and to determine where receivers should be placed. This study would also incorporate the usage of balloon tags which should be held for 48 hours.

For spill mortality sites (dam bascule gate, dam taintor gate, Cabot spillway, Cabot Station bypass), tagged eels will be injected or released into spill flow at points where water velocity exceeds 10 ft/sec, to minimize the possibility of eels swimming upstream into the headpond or canal. Passed balloon-tagged eels will be recovered below areas of spill and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data. In addition, mobile tracking of fish via boat should also be incorporated into this study.

The turbine mortality component of the study should occur in Study Year 2.

Data analyses of route selection and turbine mortality (instantaneous and latent) will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

These methodologies are consistent with accepted practice.

Level of Effort and Cost

The level of cost and effort for the downstream eel passage study would be moderate to high; silver eels would need to be collected, tagged, and released in several locations over the course of the migration season. Antennas and receivers would need to be installed at the intakes to all stations as well as at the Turners Falls dam spillway and Cabot Station bypass, and monitored regularly. Data would need to be retrieved periodically and subsequently analyzed. A multi-site route selection study conducted by the USGS Conte Lab on the Shetucket River in Connecticut cost approximately \$75,000 for the first year of study. Costs are estimated at \$100,000 per year for the Route Selection studies and \$75,000 per year for the Spill, Bypass, and Turbine Mortality/Injury Studies (personal communication Alex Haro, USGS).

The applicant did not propose any studies to meet this need in the PAD. No alternate studies were proposed.

6.11 Requested Study #11: Assessment of adult sea lamprey spawning within the Turners Falls and Northfield Mountain Pump Storage Project Area

Sea lamprey could potentially find suitable spawning habitat within the Turners Falls project reach. Currently, our understanding of how these fish utilize the existing habitat within the project reach is not well understood.

Goals and Objectives

Our goal is to determine the impacts that the Turners Falls and Northfield Mountain Pump Storage Project's operations have on this species' spawning activity and spawning success. Such an understanding can guide us as we consult with the licensee on developing solutions to mitigate impacts to sea lamprey.

The objectives for this study include:

1. Assessing the level of spawning activity by adult sea lamprey in the Turners Falls and Northfield Mountain Pump Storage Project area (downstream extent of Turners Project operation influence and upstream extent of influence of both Projects) and determine whether the operations of the Projects are affecting the success of this activity to occur.
2. Identifying areas within the Project area where suitable spawning habitat may exist for adult sea lamprey.
3. Conducting a telemetry study of sea lamprey during their upstream migration period in the spring, focusing on areas of suitable spawning habitat, and areas of known spawning events.
4. Conducting a spawning ground surveys to observe the utilization of this habitat for spawning purposes, and hence, confirm suitability.

5. Obtaining data on redd characteristics including location, size, substrate, depth and velocity.
6. Determining if the operations at Turners Falls project (dam, Station 1, and Cabot Station), downstream reaches, and Northfield Mountain Pump Storage (upstream reaches) are adversely affecting these spawning areas (i.e. if flow alterations are causing dewatering and scouring of lamprey redds).

If it is determined that the Project operations are adversely affecting the spawning success of sea lamprey, identify operational regimes that will reduce and minimize impacts to sea lamprey spawning habitat and spawning success, within the project area.

Resource Management Goals

Sea lamprey are a trust resource. As such, we are charged with protecting this species and reducing the threats this species faces in order to maintain its population.

The sea lamprey *Petromyzon marinus*, within the Connecticut River drainage, is one of New Hampshire's and Vermont's Species of Greatest Conservation Need (SGCN). Examples of threats identified in the Vermont Wildlife Action Plan (2005) include degraded spawning habitat, and habitat fragmentation.

As outlined in Vermont's Wildlife Action Plan (2005), research and monitoring needs for SGCN include monitoring and assessing populations and habitats for current conditions and future changes, and identifying and monitoring problems for species and their habitats.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act and the Federal Power Act.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information

In 2012, a total of 14,089 sea lamprey passed upstream of the Holyoke Dam. The number of adult sea lamprey passed upstream of Holyoke has ranged from 14,089 to 100,000 since 1975, when counting for that species first began. The number of sea lamprey passed upstream of Turners Falls Dam was 4,503 in 2012, with the highest reported lamprey passage count 32,035 occurring in 2008. Annual count data, when available, are provide in the PAD, but it should be noted that lamprey pass at night as well and only in recent years has the digital imaging system been in place at the Project to more accurately determine this count.

Sea lamprey are known to utilize both main stem and accessible tributary habitat consisting of larger gravel to small cobble substrate in areas with flowing water (e.g., upstream of impounded areas or in areas within impoundment that provide favorable hydraulic conditions) from which they construct their nests or redds. Sea lamprey pairs or groups (multiple fish may form an aggregate nest) can be observed building redds, or nearby recently completed redds, generally in late June, from the Sunderland Route 116 bridge upstream to the base of the Cabot Station in shallow water habitats with the preferred substrate types, where water velocities are increased due to a variety of river physical characteristics (e.g., shifts in depth contours, channel turns, islands).

The Connecticut River Coordinator (Ken Sprankle, USFWS) has observed that sea lamprey also spawn in the Connecticut River main stem upstream of the Turners Falls Dam within close proximity of the Vernon Dam (habitat adjacent to Stebbins Island, both sides of island). This species is known to utilize lower sections of tributaries, such as the Ashuelot River, Hinsdale, New Hampshire and main stem gravel bar and shallow water habitats within the Turners Falls impoundment (e.g., Massachusetts State Line).

To date no studies have been conducted that aim to identify spawning habitat and activity of sea lamprey, and corresponding water level fluctuation impacts from Project operations downstream of Turners Falls Dam as well as upstream of Turners Falls Dam and Northfield Mountain Pump Storage operation impacts.

Power company studies conducted in the late spring and summer of 2012, examined habitat conditions downstream of Turners Falls Dam, including substrate composition and select area water elevation measures (24 hour basis). The study documented in low flow conditions, Cabot Station project operations produced fluctuations in water level elevations that can range over 4 feet in magnitude (daily operation) at the USGS Montague Gage Station, to lower values of 2 to 3 feet at the Route 116 Bridge, Sunderland, MA (PAD). Similarly, water elevation measures were obtained at two sites in the upper portion of the Turners Falls impoundment where sub-daily, Project operations (Northfield Mountain Pump Storage) also resulted in changes of several feet in magnitude.

Project Nexus

The Turners Falls and Northfield Mountain Pump Storage project operations have the potential to cause direct adverse effects to sea lamprey spawning activity, spawning success, and spawning habitat. If adult sea lamprey are actively spawning in the project area, it is important to assess whether Project operations are having any adverse effects (i.e. dewatering and scouring) to these spawning activities, their redds (spawning success), and spawning habitats.

Proposed Methodology

Although a relatively new practice, the tagging and tracking of adult Pacific lamprey to determine final destination, has been successfully conducted in the Columbia River. See Noyes *et al.* 2012.

As part of the Well Hydroelectric project (FERC No. 2149), Pacific lamprey spawning ground surveys were conducted to determine project effects on spawning success.

Level of Effort and Cost

The estimated level of effort and costs for this recommended study is expected to be moderate to high. FirstLight did not propose any alternative studies in its PAD to address this specific issue.

6.12 Requested Study #12: 3-dimensional computational fluid dynamics (CFD) modeling in the vicinity of fishway entrances and upstream of powerhouse forebays

Very complex flow fields occur in the vicinity of fishway entrances, powerhouse tailraces and upstream of the entrance to powerhouse intakes. In the case of fishway entrances it is important to ensure that adequate attraction water is present, that velocities are within an acceptable range, and that a certain amount of differential between the entrance pool and the river itself exists such that fish not only find the entrance but actually enter it. CFD modeling can greatly assist in

determining to what extent favorable entrance conditions exist in front of a fishway. With respect to downstream passage, when a downstream bypass facility is present, it is important to understand the direction and magnitude of flow fields that are upstream of the turbine intakes such that some level of flow exists that can guide fish towards the bypass. Also, if excessive velocities occur in front of the turbine intakes, this can lead to entrainment and impingement problems for migrating fish.

Goals and Objectives

The goal of this study is to determine the flow field conditions that exist in and around the fishway entrances, and upstream of both Turners Falls powerhouses (Station 1 and Cabot). The information from this request is meant to be coupled with data from the telemetry study such that a comprehensive understanding of fish behavior is developed.

The objective of this study is to develop a series of maps that show velocity magnitude at discharges that have been agreed upon by the resource agencies and the licensee. With respect to upstream passage, the results will show approach velocities and orientation within the approach zone of the fish that may create a response in fish. This information can be coupled with telemetry data (Study Request #7, shad telemetry study) and passage counts to understand which conditions are optimal for guiding migrating fish to the fishway entrances and for stimulating fishway entry. With respect to downstream migration, the results will show velocities and orientations in front of each powerhouse. At Cabot Station, the results will indicate to what degree flow directs downstream migrating fish towards the surface bypass weir. At Station 1, the results should identify the magnitude of velocity in front of the turbine intakes.

Resource Management Goals

The management goals of this study request are to obtain information that will help assist in designing effective upstream fishways for upstream migrating trust species and to reduce impingement, entrainment and delay for downstream migrating fish. CFD models are a relatively cost effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating and which spillway gates are releasing water can all be examined. As stated, the results from this study are meant to be used along with the data generated from the telemetry study. The combined analysis from these two data sources can help assess which flow conditions are most advantageous for migrating trust species to successfully pass the project in a safe, timely and effective manner current and proposed conditions.

As for downstream migration of adult and juvenile shad, and adult eel, the results from the models will reveal flow magnitude and direction in front of each powerhouse. Given the limited information that currently exist on survival through Cabot and Station 1, our management goal is to direct as many downstream migrating fish as possible towards the uniform acceleration weir and downstream bypass. With respect to upstream passage, we want to maximize the number of fish that find and enter the ladder entrances.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act and the Federal Power Act.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and the Need for Additional Information

To date, no CFD modeled data exist in front of either fishway, nor do they exist in front of either powerhouse. Some preliminary modeling has been done downstream of the Gatehouse, but changes to the gatehouse entrances would require updated modeling. It is our understanding that the licensee has worked with the firm Alden to develop a CFD model of the upper power canal and that elevation survey data from the power canal also are available. Detailed 2-dimensional movement data on shad are available from observations made between 2003 to 2005 and 2010 to 2012. By coupling and analyzing these two data sets, flow and fish movement, we believe this will have substantial benefits to our management efforts.

When designing upstream passage structures, a site assessment is critical. The development of these models gives resource agencies valuable information into the hydraulic cues which may elicit a response from upstream migrants. For downstream passage, the USFWS has approach velocity guidelines; the output from these models would inform the resource agencies under what conditions appropriate approach velocities are being met and when they are being exceeded.

Project Nexus

The Turners Fall project has direct impacts to upstream and downstream migrating shad and eel. Our mandate from the Federal Power Act is that migrating fish have access to safe, timely and effective passage at hydro-electric facilities.

With respect to upstream migration, the auxiliary water system (AWS) plays a critical role in determining whether or not fish are attracted to the entrance. The results from this study would allow us to assess how well the AWS is performing and under what conditions it attracts the most fish.

With respect to downstream migration, as a general rule, fish tend to follow the flow. If flow fields are directing fish towards the turbine intakes, the results from this study will indicate that. The development of a CFD model under existing conditions also informs the design of future modifications. The development of a CFD model could be used to improve the survivability of downstream migrating shad and eel.

Proposed methodology

A 3-dimensional CFD model has become an increasing common standard of analysis at hydro-electric projects around the nation. Within the Northeast region, we have seen these types of models developed at the Holyoke (P-2004), Brunswick (P-2284), Shawmut (P-2322), Milford (P-2534) and Orono (P-2710). We would expect to engage with the licensee in terms of determining the appropriate area and flows to be modeled. We expect that the spatial extent of the model at each study site will vary. Given the large number of ways that output from these models can be presented and the near infinite number of flows that could potentially be modeled, we would expect to consult with the licensee to reach agreed upon modeling efforts and scenarios to be examined.

Level of Effort and Cost

The cost of developing, running and testing a CFD model can vary tremendously; one large variable to determining the cost is based on the amount of existing bathymetric data the applicant currently has access to. It has been estimated that the cost of each CFD model could run as high as \$50,000 assuming no bathymetric data currently exists (personal communication Brett Towler, USFWS). Proactive communication with resource agencies will reduce the cost and iterative effort. The level of effort is commensurate with that of the other projects listed above and is warranted considering the long-term of the license renewal. FirstLight did not propose a study to address this issue and it did not propose an alternate study.

6.13 Requested Study #13: Entrainment of migratory fish from the Connecticut River into the Northfield Mountain Pump Storage Project

The turbines used to pump water into the Northfield Mountain Reservoir and used to generate power from water released from this reservoir have the potential to entrain fish migrating upstream and downstream along the Connecticut River. Currently, our understanding of this potential impact is not well understood.

Goals and Objectives

The goal of the study is to determine the impact of NFMPS Project during pumping on entrainment of juvenile American shad, adult shad, and adult American eel, including early life stages.

The objective of the study is to quantify the number of migratory fishes entrained at the NFMPS intake on an annual basis in order to evaluate potential impacts to Trust species in the Turners Falls pool and migrants moving through the project area. This should be done through a combination of hydroacoustic monitoring and netting using various gear types to quantify and identify species of different life stages.

Resource Management Goals

The CRASC developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

Based on the CRASC plan, we seek the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

The ASMFC has developed two documents related to the management of American eel:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the CRASC developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Specific to resident riverine and migratory fish entrainment, our goals are:

1. Minimize current and potential negative project operation effects such as turbine entrainment that could hinder management goals and objectives.
2. Minimize project-related sources of mortality to resident and migratory fishes in order to restore natural food web interactions and ecosystem functions and values.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*)

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

Limited project specific information exists regarding entrainment of fish and aquatic organisms at the NFMPS facility. As part of a Memorandum of Agreement between then-owner NUSCO and regulatory agencies, NUSCO conducted studies to determine the impact of NFMPS station on anadromous fishes, including Atlantic salmon, American shad, and blueback herring. Results of a pilot study conducted in the fall of 1990 indicated that trap netting at the intake was ineffective at collecting fish. Gill netting and boat-shocking did result in collection of some juvenile shad, but further refinement in both methods was recommended to improve

effectiveness. A total of 78 fish were collected at the intake (77 of which were American shad) by gill netting and 11 shad were collected by boat electrofishing. Hydroacoustic monitoring was deemed an effective method for monitoring entrained fish during pumpback operation. Hydroacoustic sampling over a two-week period (September 12-27, 1990) produced hourly entrainment estimates that cumulatively equaled 14,816 fish.

Based on the results of the pilot study, NUSCO developed a two-year plan to quantitatively determine the number of shad and salmon entrained at NFMPS station. In 1992, an entrainment study targeting juvenile American shad life stages was conducted in the lower (mainstem river) and upper reservoirs of NMPS. The study used several gear types to quantify egg through juvenile shad densities in different areas. Entrained juveniles were sampled using an upper reservoir net. Pumping operations were modified to only run three (77% of sample time) and sometimes two (23% of sample time) of the station's four units during the study and effort was limited to a total of 80 hours over a period spanning 9 August through 27 October (80 days). An estimated total of 1,175,900 shad eggs, 2,744,000 yolk-sac larvae, 10,525,600 post yolk-sac larvae, and 37,260 juveniles were reported entrained.

An additional study request seeks to obtain a more accurate documentation of all fish species inhabiting or utilizing the Turners Falls impoundment.

Project Nexus

Entrainment of fish and aquatic organisms associated with water withdrawal and hydroelectric operations has been documented to result in injury or death of entrained organisms. Migratory pass through the project area directly in front of the pump intakes. These organisms may be entrained and thus exposed to passage through the project pumps and reservoir supply tubes. How far these species and life stages may be drawn from, on a pumping cycle or over the course of time (repeated daily cycles of pumping and discharge), in relation to habitat and river conditions is unknown. Regardless of whether fish survive the pumping process, they are lost to the Connecticut River system. Depending on the species, life stages, and numbers entrained, this loss could impact the ecosystem productivity of the Turners Falls pool and may hinder restoration goals for diadromous fishes.

Previous entrainment studies have been conducted at the project. Those studies, which were done 20 years ago, documented entrainment of American shad and Atlantic salmon at the project, included over 13 million yolk sac and post yolk sac larvae of American shad. This level of entrainment is cause for concern, not only due to the resultant loss of potential adult returns, but for the important role early life history phases and juveniles play in their ecological contributions to the system (e.g., trophic interactions).

Since the previous studies were conducted, operations at the NFMPS facility have changed (e.g., the project increased the efficiency of its turbines, raising the pumping capacity from 12,000 cfs up to 15,000 cfs), as have river conditions (e.g., Vermont Yankee has increased its thermal discharge and the Vernon Project has increased its station capacity). Further, the PAD indicates that FirstLight will evaluate the feasibility of utilizing an additional 3,009 acre-feet of storage capacity to generate an additional 1,990 MWhs (this represents a 23% increase over existing storage and stored generation levels). While not specified in the PAD, increasing storage and generation would mean longer periods of both pumping and generation at NFMPS. In addition, anticipated improvements in fish passage at the Turners Falls project will result in increased juvenile production above the NFMPS. These factors, individually or cumulatively, could

increase the potential for entrainment at NFMPS station. Evaluation of the fish behavior and potential for entrainment and impingement impacts is needed to inform a decision on the need for downstream fish passage and protection measures in the license and contribute to an administrative record for potential Section 18 fishway prescriptions.

Proposed Methodology

Previous studies used varying methodologies for determining entrainment. The 1990 study concluded that hydroacoustic monitoring at the intake was a viable method for determining entrainment of later life stages, but does not allow for identification of the species being entrained. While trap netting was ineffective at collecting fish near the intake, gill netting and boat shocking did capture some fish. Both may prove to be viable sampling methods; however it is likely that additional testing and gear refinement will be necessary.

The 1992 study used nets at the pump discharge location into the upper reservoir to collect entrained fish. Testing showed that this method was only 10% efficient. Plankton netting in the nearfield area of intake was used to estimate entrainment of ichthyofauna. It is likely that a combination of methods would provide the most reliable results (e.g., hydroacoustic monitoring at the racks during pumpback operations, variable gear sampling in the vicinity of the intake immediately prior to initiation of pumpback operations to determine species composition, and plankton netting in the nearfield area of the intake to obtain information on entrainment of ichthyofauna). As these methodologies have previously been utilized at the site, they are consistent with accepted practice.

Although a previous entrainment study was conducted, we believe it should be repeated, using a modified study design. The 1992 study only collected a total of 330 juvenile shad over a three-month period (resulting in an overall estimate of 37,260 juveniles entrained, after accounting for poor net efficiency); whereas the hydroacoustic study conducted in 1990 estimated nearly 15,000 fish in 15 days (while these fish were not identified, 77 of the 78 fish collected at the intake during the study were juvenile shad). It also should be noted that in the 1992 study, juvenile shad were collected on the first day of sampling, indicating that the sampling did not begin early enough, which would mean the results are an underestimate of the number of juvenile shad that were actually entrained. In 1990, 27,908 adult shad passed the Turners Falls gatehouse, while in 1992 over 60,000 shad passed gatehouse. The fact that the numbers entrained were so variable between study years argues for repeating the study, using a combination of previously-used methodologies.

The study will require deployment of at least five hydroacoustic transducers (one per rack face and one offshore). These transducers would be operated during every pumping cycle from April 15 through May 14 to assess riverine fish entrainment, from May 15 through July 15 for spent adult shad, and from July 16 through November 30 for entrainment of adult silver eels, juvenile American shad, and riverine fishes. Concurrent field sub-sampling at the intake to determine species composition would need to occur.

Level of Effort and Cost

We know of no other tool that will provide for this type of assessments for all fish species and organisms that may pass through the project. Cost is expected to be high. The study will require deployment of at least five hydroacoustic transducers (one per rack face and one offshore). These transducers would be operated during every pumping cycle from April 15 through May 14 to

assess riverine fish entrainment, from May 15 through July 15 for spent adult shad, from July 16 through August 14 to assess riverine fish entrainment and from August 15 through November 30 for entrainment of adult silver eels and juvenile American shad. Concurrent field sub-sampling at the intake to determine species composition would need to occur. Data analysis would require moderate effort.

The applicant did not propose any studies to meet this need in the PAD.

6.14 Requested Study #14: Study of shoreline erosion caused by Northfield Mountain Pumped Storage (NMPS) operations

With approval for construction of the Northfield Mountain Project in 1968, and the use of the Turners Falls Impoundment as the lower impoundment for pumped storage operations, the Turners Falls Impoundment was enlarged to provide an additional 12,600 acre-feet of useable storage by raising the normal water surface elevation approximately 5.4 feet to elevation 185 feet mean sea level at the Turners Falls Dam. Operations began in 1972; since then all project operations have operated under this raised dam environment. The operation of NMPS causes alterations to the river as a direct feature of plant functionality. The alterations include: 1) daily fluctuating pond levels which at times in some places can exceed six feet (the license allows fluctuations up to 9 feet measured at an undisclosed location near and upstream of the Turners Falls dam), 2) altered flow and velocity profiles of river and 3) changes to the downstream hydrograph. Elevation data of the head pond in Appendix E of the PAD indicate that stage changes of 2 to 3 feet during the summer of 2012 were not uncommon. The additional 5.4 foot elevation increase in the headpond resulted in motorized boat traffic becoming more popular and makes the use of larger boats more possible. The presence of motorized recreational boats increases wake energy that can accelerate bank erosion rates.

Raising the level of the headpond can saturate bank soils. These same soils can quickly become dewatered when the headpond is lowered. Repeated saturation and dewatering of banks can lead to bank instability which in turn can lead to bank failure and eroded material entering the river. See Field (2007) for an extended discussion on bank erosion and failure mechanics. Elevated levels of turbidity and suspended solids in the water column can diminish rearing and migratory habitat for fish. When too much fine grain material is deposited on channel bed substrates, particularly those substrates used for spawning, spawning success of resident and migratory fish is compromised, potentially reducing recruitment and carrying capacity.

Goals and Objectives

The goals of this study request would be to determine the environmental effects of the presence and operation of the licensed facilities on river bank stability, shoreline habitat, agricultural farmland, wetland resources, bed substrate, and water quality in the Turners Falls impoundment. We recognize that data from other studies will be made available and we think that the data from these other studies could be used to help meet the objectives of this study request.

Objectives of the study include the following

1. Calculate the total volume of eroded material, calculate resulting nutrient loading of eroded material, and document and describe the three dimensional changes to the bank, including lateral bank recession, changes to bank slope, and the presence and subsequent inundation of pre-project beaches and shoreline since the Turners Falls Dam was raised and the Northfield Mountain Pumped Storage facility came on-line.

2. Document and describe the changes to banks upstream and downstream of riverbank restoration projects, including bank recession.
3. Identify the changes that have occurred to bed substrate as a result of fine grain material being eroded from the banks and being deposited on the channel bed.

Relevant Resource Management Goals

Our management goal is to ensure high quality habitat for migratory diadromous fish. Shortnose sturgeon, American shad and American eel all require suitable spawning, rearing, migratory and foraging habitat. Eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turner's Falls headpond, the bypass reach and downstream of the Turner's Falls project reduces the quality of habitat for these species. Elevated levels of suspended sediment are associated with a diminution in water quality which also affects the quality of habitat encountered by trust resource species.

In addition to habitat effects, soil erosion contributes to nutrient loading. In 2001, the U.S. EPA approved New York and Connecticut's Long Island Sound (LIS) dissolved oxygen Total Maximum Daily Load. As a result, the New England Interstate Water Pollution Control Commission (NEIWPCC) established the Connecticut River Workgroup and the Connecticut River Nitrogen Project. This project is a cooperative effort involving staff from NEIWPCC, the states of Connecticut, Massachusetts, New Hampshire, and Vermont, and EPA's Region 1 and Long Island Sound (LIS) offices. All are working together to develop scientifically-defensible nitrogen load allocations, as well as an implementation strategy, for the Connecticut River Basin in Massachusetts, New Hampshire, and Vermont, which are consistent with Total Maximum Daily Load allocations established for LIS. Since its inception, the Connecticut River Workgroup has participated in a number of projects to better understand nitrogen loading, transport, and reductions in erosion.

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and Need for Additional Information

The PAD makes reference to several studies in section 4.2.4 including the Erosion Control Plan (Simons & Associates, 1999), previous Full River Reconnaissance studies (1998, 2001 – maps but no report generated, 2004, and 2008), Field Geology Services' 2007 fluvial geomorphic investigation of the Turners Fall headpond, and 2012 investigations by Simons & Associates.

Field Geology Services' 2007 investigation provided several good recommendations for future work in section 9.3 of this report which, if implemented, could provide for: a) an improved understanding of the causes of erosion; b) more accurate monitoring of erosion; and c) more successful bank stabilization efforts. This document is a good point of reference. Conversely, The Simons & Associates' (2012) documents are qualitative and based on several unstated assumptions that may not be valid. Full River Reconnaissance efforts have been undertaken using varying methodologies, making for difficult comparisons from one report to the other.

We believe that these existing studies do have data that can be useful if certain new analyses are undertaken. These analyses of existing data would help fill in our gaps of understanding of bank erosion in the Turners Fall headpond. We are also asking for some additional field collected data. With the existing information, it should be possible to better display what changes have occurred to streambanks over time. Current Geographic Information System (GIS) software

allows for various types of data to be assembled into a map and into a database such that change over time analysis can be conducted fairly easily. The change over time analysis is a critical analysis that is needed, and was already started under Field (2007).

Photos that have been taken at or near the same location but at different times exist. For example, the last three Full River Reconnaissance efforts have included continuous videotaping of the river banks with locational information. With these data, “snapshots” of the bank at various locations could be extracted and compared over time. Field (2007) photo locations could be re-shot as well. This existing information should be presented such that it is easy to discern where the photo was taken and what changes have occurred over time. A comparison of the bank every 100 ft could be compared over the years.

Historic aerial photography for the Turners Fall headpond should be gathered and analyzed. Examples of good photographic datasets include the Field 2007 appendices and 1929 aerials. The location of the shoreline over time should be noted such that it is easy to discern where bank retreat has been most severe and where the river has been relatively stable since the earliest aerial photograph was taken.

Very little turbidity data for the Turner’s Falls headpond, the bypass reach or stretches of the Connecticut River downstream of the Turner’s Fall project exist. Thus far, implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) has yielded few results, and many technological difficulties (see *2012 Sediment Management Plan – 2012 Summary of Annual Monitoring* dated November 30, 2012). Suspended sediment monitoring equipment is installed at the Route 10 Bridge upstream of the project and inside the powerhouse, theoretically taking readings representative of pumping and discharging through the turbines. An analysis of how turbidity might change relative to rapidly changing headpond levels would be very useful information.

Project Nexus

The construction of the NMPS project was contingent upon the Turner’s Falls project raising the dam crest elevation by 5.9 feet. The NMPS project operations rely on the Turner’s Falls headpond as the source of water to be pumped and to be discharged into. The importance of this river reach to the NMPS operation is made clear by FirstLight’s reference to this portion of the river as the “lower reservoir.” Daily pumping and discharging changes the ponded elevation of the Connecticut River which in turn leads to bank material that repeatedly becomes saturated and then dewatered. Weakened bank material can then become eroded and the fine grain material from the banks can enter the water column and be transported in suspension in the river and eventually settle onto bed material. The raising of the Turner’s Falls headpond also made recreational boating more popular, including the introduction of large, high-horsepower powerboats that were not previously present. Because of the fluctuating water levels, boat wakes impact the shoreline to a much greater extent than would occur if levels were more constant, thus exacerbating both the effects of the wakes and the fluctuating levels. For these reasons, erosion caused or contributed by NMPS project operation can negatively affect spawning, rearing and migratory habitat for trust species and the endangered shortnose sturgeon. The requested study will help inform the Commission when contemplating mitigation measures and or operational modifications.

Proposed Methodology

1. This study should determine the net soil loss in cubic yards between 1970 and the present; a density estimate of the eroded material should also be provided. Provide an analysis of where the greatest loss has occurred, location of proximity to the tailrace, soil type, riparian land use, and vegetative cover in that area. Calculate nutrient loadings (nitrogen and phosphorus compounds) to the river system based on soil loss. Obtain copies of the original survey plans for the project, and complete a new survey using the same landmarks used previously. The Field (2007) report states on page 11 that the original survey plans of the river are still retained by Ainsworth and Associates, Inc. of Greenfield MA. Use pre-operation aerial photos and current aerial photos to complete a 10-foot topographic map of the section of river between Turners Falls Dam and Vernon Dam and the 200-foot buffer regulated under the Massachusetts Rivers Protection Act. The Field (2007) report on page 11 states that Eastern Topographics, Inc. determined that sufficient information is known about the 1961 aerial photos (e.g., height of airplane) to create a 10-foot topographic map of that time period, and that 1961 aerial photos could be accurately overlaid with recent aerial photos. Field (2007) states that this analysis would enable a more reliable determination of small-scale shifts in channel position and changes in bank height that may have resulted from the erosion of a low bench that previously existed along portions of the river. Among other things, create a single map showing areas of erosion and deposition, and also overlay the Field report's hydraulic modeling analysis of the river channel.
2. With respect to the January 22, 2013 submittal from FirstLight to FERC regarding its long term monitoring transects in the Turners Fall impoundment, we ask that any data errors (as discussed in Field, 2007) and problems that have occurred over the years at each site be mentioned. We also ask that that an analysis for each cross section extending to the top of the bank and including a portion of the floodplain be provided.
3. Take the information presented in Figure 4.2.3-1 "Soils in the vicinity of Turners Falls and Northfield Mountain projects" in the PAD and convert from 63 categories to just a few that are defined in a key that will allow readers to understand which soils are easily erodible, which aren't, and where there is bedrock along the banks.
4. Complete detailed surficial mapping (topographic map or LIDAR) to identify the various geomorphic surfaces, height of benches/terraces above the river level, and types of sediments underlying the surfaces. This will allow one to determine how erosion varies with geomorphic conditions. One could then normalize the amount of erosion to a specific type of bank material/geomorphic surface/terrace.
5. Another information request covers the range of daily water level fluctuations. In this study request, we ask for an analysis on the degree to which boat wakes increase that fluctuation range. The task would be to observe boat wakes under a range of boat sizes and flow rates on the river. We recommend the 2007 Field report recommendation which states, "A more thorough study of boat waves is merited to better document how many boats use the Turners Falls Pool, how fast they travel, the type and size of waves they produce, and their impact on shoreline erosion."

A component of this study request is not necessarily for new data, but for existing data to be presented in a more clear, coherent and comprehensive manner. All existing photographs of banks that have been collected either by FirstLight, on behalf of FirstLight or on behalf of the Franklin Regional Council of Governments Streambank Erosion Committee should be georeferenced in such a way such that it is easy to discern where the photograph was taken and

the date should be easily discernible as well. These photos should be presented in a manner that makes it easy to visually see how a particular section of bank has changed over time. Providing geographic context for photographic data of river banks and making these photos comparable over time should be standard practice. The 2007 Field report contains the following recommendation on page 47: “An attempt should be made to overlay the 1961 aerial photographs with a current flight and to create a topographic map from the 1961 flight. The feasibility of this effort has been confirmed by Eastern Topographics, Inc. This effort will identify the previous extent of the low bench and identify areas of the most significant bank recession the past 45 years.” Given that this statement was written in 2007, we request that that the analysis is extended to current conditions.

Given the complexity of this study request and the expertise necessary to implement it, we request that the resources agencies be involved with the selection of the hired consultant.

Level of Effort and Cost

The level of effort to compile existing information and to make the data available in a map and searching for existing bed substrate material data is a simple task that can be completed with little effort. The level of effort for the bed sampling work will vary based upon how much existing historic information exists. Much of the effort of this study request is essentially office work that compiles and better presents existing data. While an estimate on the amount of field time required is difficult to make, we estimate that up to two weeks of field work could be required and some of the data collection could be done while other field studies are occurring.

RE: Study Requests for FERC Hydroelectric Projects P-1889 (Turners Falls) and P-2485 (Northfield Mountain)

Dear Secretary Bose:

As the agency responsible for protecting fish and wildlife resources in New Hampshire, the New Hampshire Fish and Game Department (NHFGD) monitors and attempts to reduce the impacts of hydroelectric facilities on fish and wildlife species and their habitats. The mission of the NHFGD is to conserve, manage and protect the state's fish, wildlife and marine resources and their habitats, and to provide the public with opportunities to use and appreciate these resources. The NHFGD's 1998-2010 Strategic Plan contains four goals relevant to the relicensing process under the Federal Energy Regulatory Commission (FERC). These goals are to ensure that New Hampshire:

- 1) has a wide range of naturally occurring habitats and healthy, naturally functioning ecosystems.
- 2) has abundant and varied fish, wildlife, and marine species at levels that ensure sustainable, healthy populations.
- 3) has fish, wildlife, and marine populations that support desirable levels of hunting, trapping, fishing, and wildlife viewing.
- 4) Human activities and land uses are compatible with desired population and recreational goals for fish, wildlife, and marine species and the ecosystems that sustain them.

Participation in the relicensing process for hydroelectric projects falls under one of the many strategies outlined in New Hampshire's Wildlife Action Plan. Wildlife Action Plans, completed in 2005, were required from each state by the United States Congress as a proactive strategy to "conserve wildlife and vital natural areas before they become more rare and more costly to protect". New Hampshire's Wildlife Action Plan contains three objectives relevant to the hydropower relicensing process.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Objective 507: Restore or maintain natural flow regimes.

Objective 508: Restore and maintain watershed continuity.

Objective 701: Protect riparian / shoreland habitat and other wildlife corridors.

In addition to these objectives, the New Hampshire Wildlife Action Plan identifies a number of fish and wildlife species of concern, which may be impacted by the projects under review. We hereby submit the New Hampshire Wildlife Action Plan to the FERC for consideration in determining whether it qualifies as comprehensive plans pursuant to Section 10(a)(2)(A) of the Federal Power Act. The complete New Hampshire Wildlife Action Plan is available online at: http://www.wildlife.state.nh.us/Wildlife/wildlife_plan.htm.

The NHFGD has reviewed the Preliminary Application Documents and Scoping Documents for the relicensing of the following hydropower projects owned by FirstLight Power Resources:

Northfield Mountain
FERC Project No. 2485

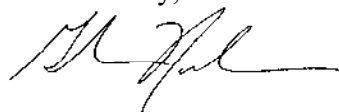

Turners Falls
FERC Project No. 1889

The NHFGD supports the following study requests submitted by other partners within the Connecticut River watershed. Although the two FirstLight projects (Turners Falls and Northfield Mountain) are not located in the New Hampshire portion of the Connecticut River, we feel it is prudent to comment on these projects and support study requests related to these projects because the FirstLight projects have the potential to impact fish migrating to and from New Hampshire waters. For example, American eel, American shad and sea lamprey all have to successfully migrate upstream past the FirstLight projects in order to reach New Hampshire waters. Additionally, fish that are reared (American shad and sea lamprey), spawn (American shad), and grow to maturity (American eel) in New Hampshire portions of the Connecticut River watershed all have to successfully migrate downstream past FirstLight projects in order to complete their life cycle. Finally, the influence of the Turners Falls Dam extends into New Hampshire portions of the Connecticut River.

The following formal study requests will expand on the information presented in each Pre-Application Document (PAD) and lead to informed management decisions intended to reduce impacts on fish and wildlife. It is understood that there is overlap between some of the requested studies, and where appropriate, the NHFGD supports the combination of studies to reduce cost and effort as long as the goals and objectives within each individual study proposal are still achieved.

Thank you for this opportunity to comment.

Sincerely,

Glenn Normandeau
Executive Director

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Study Request 1: Telemetry Study of Upstream and Downstream Migrating Adult American Shad to Assess Passage Routes, Effectiveness, Delays, and Survival (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

Assess behavior, approach routes, passage success, survival, and delay by adult American shad as they encounter the projects during both upstream and downstream migrations, under permitted project operations conditions, proposed operational conditions, and study treatment operational conditions at First Light Power's Turners Falls and Northfield Mountain Pumped Storage projects and TransCanada's Vernon Project. There are multiple fishways and issues related to both upstream and downstream passage success at the projects. Some of these issues at the Turners Falls Project are similar to and/or pertain directly to the Northfield Mountain and Vernon projects. Therefore, it is reasonable to address passage issues at all projects in a similar manner.

Telemetry Study - This requested study requires use of radio telemetry using both radio and Passive Integrated Transponder (PIT) tag types to provide information to address multiple upstream and downstream fish passage issues. The following objectives shall be addressed in these studies:

- Assessment of any migration delays resulting from the presence of the dam and peaking flow operations of the Turners Falls Project;
- Determine route selection and behavior of upstream migrating shad at the Turners Falls Project under various spill flow levels (e.g., movement to the dam, attraction to Cabot Station, attraction to Station 1 discharge, movement between locations, delay, timing, etc.). A plan and schedule for dam spill flow releases will need to be developed that provides sufficient periods of spill flow conditions, and various generating levels from Turners #1 Station coupled with Cabot Station generation flows (e.g., treatments will require multiple days of consistent discharge). Evaluated spill flows should include flows between 2,500 – 6,300 cfs, which relate to bypass flows identified as providing spawning opportunities for shortnose sturgeon in the lower bypass reach at the Rock Dam. (Kieffer and Kynard 2012). Sturgeon spawning and upstream shad passage occur concurrently;
- Assess near field, attraction to and entrance efficiency of the Spillway Ladder by shad reaching the dam spillway, under a range of spill conditions;
- Evaluate the internal efficiency of the Turners Falls Spillway Ladder;
- Continue data collection of Cabot Station Ladder and Gatehouse Ladder efficiency, to include rates of approach to fishway entrances, entry into fishways, and passage through them, under different operational conditions that occur in these areas;
- Evaluate modifications to the Cabot and/or Spillway fishways recommended by the Service if they are implemented;
- Assess upstream migration from Turners Falls to the Vernon Dam in relation to Northfield Mountain's pumping and generating operations and Vernon Project peaking generation operations. Typical existing and proposed project operation alterations should be evaluated;
- Assess near field, attraction to and entrance efficiency of the Vernon Dam Ladder;
- Assess internal efficiency of the Vernon Dam Ladder;
- Assess upstream passage past Vermont Yankee's thermal discharge (also located on the west bank of the river 0.45 mile upstream of fish ladder exit)
- Assess upstream migration from Vernon Dam in relation to the peaking generation operations of the Bellows Falls Project. Typical existing and proposed project operation alterations should be evaluated;

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

- Determine post-spawn downstream migration route selection, passage efficiency, delays and survival related to the Vernon Project, including evaluation of the impact of the Vermont Yankee heated water discharge plume on downstream passage route, migrant delay/timing, efficiency and survival;
- Assess impacts of Northfield Mountain operations on up- and downstream adult shad migration, including delays, entrainment, and behavioral changes and migration direction shifts under existing and proposed project operations;
- Determine downstream passage route selection, timing/delay, and survival under varied project operational flows into the power canal and spill flows at Turners Falls Dam;
- Determine downstream passage route selection, timing/delay in the canal, Cabot Station fish bypass facility effectiveness, and survival of Cabot-bypassed adult shad that enter the Turners Falls Canal system;
- Compare rates and or measures of delay, movement and survival etc., among project areas or routes utilized (e.g., spill at dam vs. power canal) under the range of permitted and proposed conditions; and
- Utilize available data sets and further analyze raw data (e.g., 2003- 2012 Conte Lab Studies) where possible to address these questions and inform power analyses and experimental design.

Information to address all of these questions would rely on the tagging of upstream migrating adult shad at Holyoke Dam and releasing them to migrate naturally from Holyoke through the Turners Falls and Vernon projects and back downstream after spawning. Additional tagged individuals would likely need to be released farther upstream (Turners Falls Canal, upstream of Turners Falls Dam, and upstream of Vernon Dam), to ensure that enough tagged individuals encounter project dams on both upstream and downstream migrations, that these individuals are exposed to a sufficient range of turbine and operational conditions to test for project effects, and to provide adequate samples sizes for statistically valid data analyses to address the many objectives listed. This study will require two years of field data collection to attempt to account for inter-annual variability in river discharge and water temperatures.

Evaluation of Past Study Data- In addition to collection and analysis of new telemetry data, substantial data has already been collected at Turners Falls from multiple years of passage assessments conducted for First Light by U.S. Geological Survey's Conte Anadromous Fish Research Center (Conte Lab) researchers and there are also data from the 2011 and 2012 full river study conducted by the Conte Lab that address Turners Falls, Northfield Mountain and Vernon project migration and passage questions that have not yet been analyzed. These data include several million records each year from more than 30 radio telemetry receivers deployed between Middletown, CT and Vernon Dam. This data will provide substantial information free from the field data collection costs and therefore should be analyzed as part of this study. This data analysis should be completed in 2013 to help inform the design of subsequent field studies.

Evaluation of Methods to Get Shad Past Cabot Station for Spillway Passage at the Turners Falls Dam – The poor passage efficiency of the Cabot Ladder, the first and most used fishway encountered by shad arriving at the Turners Falls Project, and at the entrance to the Gatehouse Ladder, which all Cabot fishway-passed fish must use, has resulted in very poor overall shad passage efficiency at the project. An alternative to passing fish at the Cabot Station is to install a fish lift at the dam that would put fish directly into the Turners Falls pool, thereby eliminating problems with the Cabot Fishways, and the Gatehouse Fishway entrance and the variable passage efficiency of the Gatehouse Fishways. For this to be effective, attraction of shad to the Cabot Station discharge and associated delays would need to be overcome. It is possible that spillway flow releases coupled with behavioral measures at Cabot Station that

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

dissuade shad from that tailrace could achieve this end. In order to assess the possibilities, we recommend the following study:

1. A literature search and desk-top assessment of the possible behavioral measures that could be effective in getting shad to pass Cabot Station tailrace and continue upstream to the dam.
2. Based on results of the desk-top assessment, possible evaluation of behavioral measures that are likely to be effective.
3. Field evaluation of the effect of different levels of spill at the dam that would induce fish to move past the Cabot Station into the bypass reach and up to the dam (as noted in objectives).

Besides passage success and delays at passage facilities, these studies would assess the impacts of project operations on migration passage delay, route, timing, injury, mortality, and passage structure attraction, retention, and success. Of particular interest will be fish behavior during periods when flow releases from the project increase from the required minimum flows to peak generation flows and when flows subside from peak generation flows to minimum flows and the operation of NMPS in pumping and generation modes.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually. (Table 1)
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

And recommendations:

Upstream Passage –

1. American shad must be able to locate, enter, and pass the passage facility with little effort and without stress.
2. Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
3. Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.

Downstream Passage –

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines,, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the least delay and best survival rate.

Based on the CRASC plan, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad movement and migration, the Service's goals are:

1. Minimize current and potential negative project operation effects such as migration delays, false attraction, turbine entrainment, survival of project passage routes, and trashrack impingement that could hinder management goals and objectives.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), Silvio O. Conte National Fish and Wildlife Refuge Act (P.L. 102-212; H.R. 794), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Atlantic States Marine Fisheries Compact (P.L. 539, 77th Congress, as amended by P.L. 721, 81st Congress), and the Atlantic Coastal Fisheries Cooperative Management Act (16 U.S.C. 5107)..

Public Interest

The requestor is a federal natural resource agency. Migratory species of fish are a trust resource for the Service due to their interjurisdictional movements. Protection and restoration of these fish is a key objective for the Service.

Existing Information

Passage of adult shad at the Turners Falls fishway complex has been the subject of intense study by the Conte Lab since before 1999. These studies have clearly demonstrated that passage through the existing fishways at Cabot and Spillway is poor (<10% in many years). Passage through the Gatehouse fishway is better, but still rarely exceeds 80%, despite the short length of this ladder. In addition to poor passage for fish entering the ladders, shad that ascend the Cabot Fishway experience extensive delays before entry into the Gatehouse Fishway. Shad that ascend Spillway frequently fall back into the canal and are also subject to these upstream delays. A new entrance to the Gatehouse Fishway installed in 2007 led to dramatic improvements in passage out of the canal (from 5% to over 50% in 2011), but passage still falls well short of management goals. In addition, shad spend considerable time (up to several weeks) attempting to pass. These delays likely influence spawning success and survival. Adult shad, unable to pass Gatehouse, experience similar delays in downstream passage, even after they have stopped trying to pass Gatehouse. Without spill, all outmigrating shad that have passed Gatehouse must enter the canal at the Gatehouse and may be subject to delays exiting the canal.

During the course of these studies a very large dataset has been compiled that could yield useful information for further improving passage of shad out of the canal in both the upstream and downstream directions. A unique feature of these data is a 2-dimensional array covering the canal just downstream of Gatehouse, documenting fine scale movements and occupancy

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

of this zone. These data should be combined with computational fluid dynamics (CFD) and real-time hydraulic data to determine how canal hydraulics influence the ability of shad to locate and enter the fishway, and to identify modifications that are likely to lead to improvements in approach and entry rates. A separate CFD modeling study is requested that includes modeling of the Gatehouse Fishway entrance are at the head of the power canal.

In addition, whole-river shad telemetry studies performed in 2011 and 2012 will likely provide useful information and should be analyzed. These data should allow quantification of delay below Turners Falls, and could help guide studies requested above. Preliminary analyses of data through 2011 have been made available to FirstLight and the resource agencies (Castro-Santos and Haro 2005; Castro-Santos and Haro 2010).

The whole-river studies have also shown that, at least in 2011, most shad that pass Turners Falls rapidly progress upstream to Vernon Dam where extensive delays also occur. Data from the 2012 study were not available at this time, but Dr. Castro-Santos stated similar patterns were noted in the data between the years on the topic of upstream delay (personal communication, Dr. Theodore Castro-Santos). Similarly, concerns relative to the downstream passage of spent shad also remain relative to delays, with existing unpublished USGS telemetry data sets suggesting this is an issue within the Turners Falls canal.

Since the first year of operation of the Turners Falls upstream fishways (1980), the percent passage of American shad annually passed upstream of Turners Falls Dam compared to the number passed at the Holyoke Fish Lift has averaged 3.6% (1980-2012 data). The highest values for this metric has not exceed 11% and are well below the noted CRASC Management Plan target range for this objective noted earlier as 40-60% on a five year running average.

Since the first year of operation of the Vernon Dam upstream fish ladder (1981), the percent passage of American shad annually passed at Vernon compared to the number passed upstream of Turners Falls Dam (Gatehouse counts) has averaged 39.4%, ranging from 0.42% to 116.4% (> 100% due to counting error at one or both facilities, unknown).

Nexus to Project Operations and Effects

Existing project operations (peaking power generation) and limited bypass flows have a direct impact on instream flow and zones of passage (migration corridors). Project flow releases affect passage route selection, entry into fishways, and create delays to upstream migration. Inefficient downstream bypasses can result in migration delays and increased turbine passage. Mortality of adult shad passing through these turbines is expected to be high (Bell and Kynard 1985), additional stresses associated with passage and delay may cause mortality as shad are unable to return to salt water in a timely manner. The project's upstream and downstream passage facilities need to be designed and operated to provide timely and effective upstream and downstream fish passage to meet restoration goals of passage to upstream habitat and maximize post-spawn survival. These factors are all critically important to the success of restoration efforts.

Methodology

Use of radio including passive-integrated transponder (PIT) telemetry is widely accepted as the best method to assess fish migratory behavior and passage success and has been used extensively to assess migration and passage issues at Turners Falls as well as other Connecticut River projects. These studies include one conducted in 2011 and 2012 by the Service and U.S. Geological Survey's Conte Anadromous Fish Research Center, which has provided substantial information related to some of the issues identified here. The requested study will build and expand on the information collected over the past two years.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

The study design must specify sample sizes, tag configurations and receiver configurations, to ensure that rates of entry and exit to the tailraces, fishways, downstream bypasses, and the bypassed reach can be calculated with sufficient precision to determine effectiveness of flow and ensonification treatments (separate Study Request). For project assessments at Turners Falls (e.g., Cabot, Spillway and Gatehouse ladder attraction and entry, route selection, operational effects), double tagged (radio and PIT) shad will be required for release from Holyoke Dam. Additional shad must be released directly into the Turners Falls Canal to support assessment of the various operational and structural conditions in effect, to be modified in this period, and proposed conditions within the Turners Falls power canal relative to entrances to the Gatehouse fishway. A related request on CFD modeling in the Cabot Station tailrace, the upper power canal near Gatehouse, and in the area around the entrance of the Spillway Ladder will address related project operational effects that will also address identified objectives in this telemetry request. Shad captured at Holyoke and tagged and release upstream of Turners Falls Dam, or tagged out of Gatehouse Ladder, would help to ensure an adequate sample size for evaluations in the vicinity of NMPS and to the Vernon Dam and the ability to address identified study objectives in those project areas. Additional tagged shad are expected to be required for release upstream of the Vernon Dam, which should ensure adequate sample for a separate study request, where shad spawn upstream of Vernon Dam as well as ensuring there is an adequate number of outmigrating spent adults to address related study objectives for adult outmigrants. The required number of tagged fish to address study objectives may be adjusted accordingly from area to area depending on target numbers (i.e., best information on resultant viable tagged fish and power analyses to detect effects) to account for typical passage rates, survival rates, and handling effects as examples.

Existing information on captured, handled, tagged fish performance (e.g., percent that drop back, unsuitable for tracking) and factors such as timing of tagging and potentially transport, must all be carefully considered to ensure an adequate sample size of healthy (e.g., viable to characterize behavior, survival, etc.) tagged fish is available to address the many questions identified in this request (as supported by a statistical power analysis). Additionally, ensuring adequate downstream adult fish sample sizes (to address project effect questions above) requires close consideration as expected losses of healthy tagged fish during upstream passage, natural mortality rates, and tagging related effects, are expected to reduce sample sizes on downstream passage objectives/questions as the season progresses. The use of single PIT tagged fish can help improve sample sizes, but will be of limited use to answer some of the passage questions we have identified.

Due to environmental variability, two years of study work will be necessary. A large array of stationary monitoring stations (radio and PIT) will be needed to address the issues identified among the project areas. A sufficient level of radio receiver and PIT reader coverage will be required, to provide an appropriate level of resolution, for data analyses, to answer these questions on project operational effects. The study will provide information on a variety of structural and operational aspects of fish migration, relative to route selection, timing, survival, and up and downstream passage attraction, retention, delay, efficiency, survival as some examples at three projects (Turners Falls, NMPS, and Vernon). The use of video monitoring may also be utilized for specific study areas such as the Spillway Ladder, to provide additional information on shad entrance activity, with the understanding of some data limitations associated with this approach (fish identification, water visibility). This study will be coordinated with the proposed study request to evaluate ensonification as a shad behavioral deterrent at the Cabot Station tailrace which will be an additional treatment of the telemetry study.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

In addition to the tagging studies, use of video monitoring of the Spillway Fishway would provide additional overall data on Spillway Fishway efficiency as all shad attempting to pass could be monitored versus just those shad that have been tagged.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The requested study is extensive and will require a substantial effort and cost to capture, PIT tag, and radio tag a sufficient number of shad at Holyoke to release at upstream locations. We are not aware of any other study technique that would provide project specific fish behavior and migration information to adequately assess existing project operations and provide insight in possible alternative operations and measures needed to address observed negative impacts to fish migration success. Cost for the entire multi-project tagging, tracking and data analysis are expected to range from \$400,000 to \$500,000 based on past Turners Falls' studies and the 2011 and 2012 shad telemetry studies. Video monitoring of the Spillway fishway would add a modest cost to this study.

Due to the fact tagged shad will move throughout the larger five project area, to varying degrees, there will be expected cost savings (e.g., radio tags) to both owner/operators, provided cooperation in study planning and implementation occurs.

Study Request 2: Evaluation of Timing of Downstream Migratory Movements of American Eels on the Mainstem Connecticut River (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

The goal of this study is to better understand migration timing of adult, silver-phase American eels as it relates to environmental factors and operations of mainstem hydropower projects on the Connecticut River.

The objectives of this study are:

1. Quantify and characterize the general migratory timing and presence of adult, silver-phase American eels in the Connecticut River relative to environmental factors and operations of mainstem river hydroelectric projects

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...”

Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species' range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to downstream passage of American eel, the Service's goals are:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

Data on timing of downstream migratory movements and rates of American eels in the mainstem Connecticut River are sparse and relatively incomplete. Preliminary data on presence of “eel-sized” acoustic targets have been collected (Haro et al. 1998) within the Turners Falls Project’s Cabot Station forebay that were somewhat confirmed by video monitoring at the Cabot Station downstream fish bypass; however, these were short-term studies, with acoustic monitoring only performed from 17 September to 5 October and video monitoring only conducted between 18 September to 22 October.

Some daily monitoring of the downstream bypass at the Holyoke Dam (canal louver array) was performed in 2004 and 2005 (Kleinschmidt, Inc. 2005, 2006, Normandeau Associates 2007); these studies also were of relatively short duration (spanning from October 5 to November 10 in 2004 and September 9 to November 11 in 2005) and the sampler was only operated at night.

To date, no other directed studies of eel migratory movements have been conducted at any location on the Connecticut River mainstem. This information gap needs to be filled, as it relates directly to when downstream passage and protection measures need to be operated.

We also note that within the past seven years, the Service has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability. On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made before any new licenses are issued for the projects.

Nexus to Project Operations and Effects

The timing of downstream migration of adult eels is poorly defined for the Connecticut River; therefore the general effects of hydroelectric project operations on eel survival to the ocean are unknown. Although separate study requests have been submitted to address project-specific downstream passage route selection, delays, and mortality of eels, general

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

characteristics of river flow and environmental conditions may have significant relationships with project operation and eel migratory success and survival. For example, eels may tend to move immediately before or during periods of significant precipitation (or consequently river flow); times at which projects may be generating at maximum capacity or spilling, which may (or may not) present a higher passage risk to eels. Conversely, periods of low flow may be associated with a significant proportion of total river flow passing through turbine units, which present additional (or different) passage risk to eels. If discrete conditions which promote eel downstream migration are known, it may be possible to take actions with respect to project operations which reduce or minimize passage risk; i.e., operation of a bypass, reduction of intake approach velocities, directed spillage through a "safe" route, etc. These studies should provide baseline information on river-specific downstream migration to predict when silver-phase eels are expected to be migrating in the mainstem Connecticut River, from which project operations could be modified to minimize passage risks.

The studies are proposed for a single or multiple sites; the results will be relevant to all sites on the Connecticut River mainstem.

Methodology Consistent with Accepted Practice

Quantification of downstream movements of American eels in river systems requires systematic sampling of migrants throughout the migratory season. This can be accomplished with traditional active trapping methods; i.e., fyke or stow net sampling, weirs, or eel racks, but these methods are technically challenging on larger mainstem rivers, due to the scale of flows that need to be sampled, difficulties in operation throughout all flow conditions, and high debris loading during fall flows. Passive monitoring of migrant eels using hydroacoustic methods offers an alternative to active trapping. However, passive monitoring requires verification of potential acoustic targets with some level of active (collection) or visual (traditional optical or acoustic video) sampling.

Two potential locations offer opportunities to conduct simultaneous passive and active sampling: the Cabot Station (Turners Falls project) canal/forebay and the Holyoke Dam forebay and canal louver/bypass system. Each location possesses a route of downstream passage which conducts a significant proportion of river flow (Cabot canal and Holyoke forebay or canal), and each has a proximal bypass equipped with a sampler so that fish can be concentrated/collected from the passage route and identified to species. Project operations do influence the relative proportion of flow (and thus numbers of downstream migrant eels) in each passage route, so numbers of eels sampled in each route represent only a proportion of the total number of eels migrating downstream within the entire river. Because the absolute proportion of eels using a specific route at any one time is unknown, numbers of eels quantified within a route must serve as a relative index of the degree of migratory movement.

This study shall quantify eel movements in either one, or preferably both, locations for two consecutive years (since environmental conditions strongly influence migratory timing of eels, which can vary significantly from year to year; Haro 2003). Eels will be quantified using methods similar to Haro et al. (1999), by continuously monitoring a fixed location at the projects with hydroacoustics. Because eels tend to concentrate in areas of dominant flow (Brown et al. 2009, EPRI 2001), the zone to be monitored should pass a dominant proportion of project flow throughout most periods of operation (i.e., forebay intake area). Hydroacoustic monitoring shall encompass the entire potential migratory season, beginning in mid-August and ending in mid-December, and shall operate 24 hours per day. Data will be recorded for later processing and archiving.

Systematic active quantification of eels at downstream bypass samplers shall be performed simultaneously with passive hydroacoustic monitoring, to verify presence of eels and relative

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

abundance of eel-sized hydroacoustic targets from the hydroacoustic data. Although daily operation of the bypass sampler could be performed, a more comprehensive technique is to monitor eels entering the bypass with an acoustic camera (i.e. DIDSON, BlueView, etc.). The acoustic camera will afford positive visual identification of eels as they enter the bypass, which is a concentration point for migrating eels. Acoustic camera monitoring will also allow monitoring to be performed 24 hours a day, and will be relatively unaffected by water turbidity (which influences effectiveness of traditional optical video monitoring). The acoustic camera system will be operated during the same time period as acoustic monitoring, and images will be recorded for later processing and archiving.

Data analyses of hydroacoustic, acoustic camera, bypass sampling, and environmental/operational data will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the downstream migrant eel migratory timing study would be moderate, given the level of cost for instrumentation, deployment, and data review/analysis. Cost is estimated at \$50,000 per year for the study.

The applicant did not propose any studies to meet this need in the PAD.

Study Request 3: Impact of Project Operations on Shad Spawning, Spawning Habitat, and Egg Deposition in the Project Areas of the Turners Falls, Northfield Mountain Pumped Storage and Vernon Project Areas and downstream from Bellow Falls Dam . (Docket Number p-1889) (Docket Number p-2485)

Conduct a field study of spawning by American shad in the Connecticut River mainstem downstream of Turners Falls Dam, in the Turners Falls Dam impoundment, in the Vernon Dam Project area, and downstream of Bellows Falls Dam to determine if project operations (including operations of the Northfield Mountain Pump Storage) negatively impact shad spawning behavior, spawning habitat use, areal extent and quality of those spawning areas, and spawning activity in terms of egg deposition in those areas.

Goals and Objectives

Determine if project operations (under the permitted and proposed operational ranges) affect American shad spawning site use and availability, spawning habitat quantity and quality, and spawning activity in the river reaches downstream from Cabot Station and in the project bypass reach of Turners Falls Dam, in the Turners Falls Dam impoundment and in relation to Northfield Mountain Pump Storage operations, downstream and upstream of the Vernon Dam, and in the project area downstream of Bellows Falls Dam. The following objectives will address this request:

- Determine areas utilized by American shad for spawning by conducting night-time visual observation of spawning activity, identify and define areas geospatially, and obtain data on physical habitat conditions effected by project operations (e.g., water depth, velocity, discharge, substrate, exposure and inundation of habitats);
- Determine project operation effects on observed spawning activity, under a range of permitted or proposed project operation conditions;
- Quantify effects (e.g., water velocity, depths, inundation, exposure of habitats) of project operation on identified spawning areas for a range of conditions, over the complete period of spawning activity;
- Quantify spawning activity as measured by night-time spawning/splash surveys and egg collection in areas of spawning activity, and downstream of these areas, to further determine project operation effects (location extent of exposure from changing water levels and flows and on associated habitats from project operations).

If it is determined that the Project operations are adversely affecting the spawning activity of American shad and impacting spawning area habitat, identify operational regimes that will reduce and minimize impacts spawning habitat and spawning success, within the project area. This study will require two years of field data to capture inter-annual variability to river discharge and water temperatures and to allow for evaluation of alternative flow regimes if year one studies determine that the present peaking regime negatively affects spawning.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running 63708.1

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM
average) at each successive upstream barrier on the Connecticut River mainstem.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes and recommendations:
2. To mitigate hydrological changes from dams, consider operational changes such as turbine venting, aerating reservoirs upstream of hydroelectric plants, aerating flows downstream, and adjusting in-stream flows.
3. Natural river discharge should be taken into account when instream flow alterations are being made to a river (flow regulation) because river flow plays an important role in the migration of diadromous fish.
4. Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account instream flow needs for American shad migration, spawning, and nursery use, and minimize deviation from natural flow regimes.
5. When considering options for restoring alosine habitat, include study of impacts and possible alteration of dam-related operations to enhance river habitat.

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Service's goals are:

1. Minimize current and potential negative project operation effects on American shad spawning and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), Silvio O. Conte National Fish and Wildlife Refuge Act (P.L. 102-212; H.R. 794), The Federal Power Act (16 U.S.C. §791a, *et seq.*), The Atlantic States Marine Fisheries Compact (P.L. 539, 77th Congress, as amended by P.L. 721, 81st Congress), and the Atlantic Coastal Fisheries Cooperative Management Act (16 U.S.C. 5107).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream from Holyoke Dam. A number of improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad population, and numbers of shad passing Turners Falls and Vernon Dam have not met CRASC management plan objectives. Population number and passage numbers past Holyoke have declined substantially from those totals in recent years, with average Holyoke passage numbers over the last 10 years of 211,850. Since historically approximately half of the returning population

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

of shad to the river passed upstream of Holyoke, recent returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management goals for the Connecticut River.

American shad broadcast spawn in congregations over shallow flats and rocky or sandy substrates (Davis et al, 1970, Mansuetti and Kolb 1953), at depths less than 10 feet and often far shallower with spawning fish swimming vigorously near the surface in a closely packed circle (Marcy 1972, Mackenzie et al 1985). Fertilized eggs drift downstream until hatching (Mackenzie et al 1985).

American shad are known to spawn downstream from the Turners Falls Project. Layzer (1974) identified 6 spawning sites from an area below the mouth of the Deerfield River (river mile 191.9) to river mile 161.7 below the Mill River in Hatfield, MA. Kuzmeskus (1977) verified 16 different spawning sites ranging from downstream of the Cabot tailrace to just upstream of the Holyoke dam (river mile 87.1). The only parameter that all spawning sites had in common was current (Kuzmeskus 1977). The Service is not aware of any more recent studies that document whether these 16 sites are still viable spawning locations for shad. We are not aware of any studies that have determined American shad spawning habitat or spawning sites upstream of Vernon Dam to Bellows Fall Dam (historic extent of upstream range).

First Light Power conducted studies in the late spring and summer of 2012, examined habitat conditions downstream of the Turners Falls Dam. The study documented that in low flow conditions, Cabot Station project operations produced fluctuations in water level elevations that can range over 4 feet in magnitude (daily operation) at the USGS Montague Gage Station, to lower values of 2 to 3 feet at the Route 116 Bridge, Sunderland, MA (PAD). Similar short-term, limited monitoring in the upper Turners Falls Dam impoundment identified water level changes due to project operations that cyclically varied several feet on a sub-daily frequency.

Nexus to Project Operations and Effects

American shad are known to spawn at five locations downstream from the Turners Falls Project from an area below the mouth of the Deerfield River (river mile 191.9) and ten other locations downstream to river mile 161.7 below the Mill River in Hatfield (Layzer 1974, Kuzmeskus 1977).

Shad spawning is likely influenced by river flow, which fluctuates greatly due to the project's peaking mode of operation. These fluctuations may impact shad spawning activity by altering current velocities and water depth at the spawning sites. Effects on spawning behavior could include suspension of spawning activity, poor fertilization, flushing of eggs into unsuitable habitat due to higher peaking discharges, eggs dropping out into unsuitable substrate and being covered by sediment deposition and/or eggs becoming stranded on dewatered shoal areas as peak flows subside.

While a number of shad spawning and egg deposition studies were conducted in the 1970s, that research was aimed at assessing the potential impact of developing a nuclear power station in the Montague Plains section of the Connecticut River. The Service is not aware of any studies being conducted specifically designed to determine if a relationship between spawning behavior, habitat use, and egg deposition and project operations effects of the Turners Falls, Northfield Mountain Pump Storage and Vernon projects and downstream of Bellows Falls Dam..

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

The Service is concerned that peaking operations may be altering spawning behavior and contributing to the failure of the Connecticut River shad population to meet management targets.

Methodology

The first year of study should examine known spawning areas downstream of the Turners Falls Dam project, to determine operation effects on shad spawning behavior, activity, and success. In areas upstream of Turners Falls Dam to the Bellow Falls Dam tailrace, the study should identify areas utilized for spawning by American shad. In the second year, should results from year one determine project operations affected spawning activity, access to habitat, or success, downstream of Turners Falls Dam, then an identical more detailed assessment (identified objectives) should be conducted in spawning areas upstream of Turners Falls Dam to the Bellows Falls Dam tailwater. Measures to reduce or eliminate any documented project operation impacts should be explored and evaluated in year two, downstream of Turners Falls Dam.

The impacts to spawning behavior would best be studied by night-time observations of actual in-river spawning behavior (Ross et al. 1993). Project discharge increases or decreases during actual observed spawning activity will provide empirical evidence of change in behaviors. The observational methodology should follow the protocol specified in Layzer (1974) and/or as described in Ross et al. (1993). The analysis should utilize the observational field data in conjunction with operational data from the projects (station generation and spill on a sub-hourly basis). To assess the impacts of changes in generation flows, the study should include scheduled changes in project operation to ensure that routine generation changes that occur during the nighttime spawning period affect downstream spawning habitats selected for study while shad are spawning. Stier and Crance (1985) provide optimal water velocities during spawning to range between 1 to 3 ft/sec.

In areas used for spawning, the characteristics of those areas (e.g., location, depth, flow, substrate) should be recorded. The effect of project operations (discharge, water velocity, inundation and exposure) should be assessed. Drift nets will be used to collect eggs to quantify egg production before and after flow changes at the spawning site.

In the reaches above the Turners Falls dam, night time observations of splashing associated with shad spawning should be done in each reach as sufficient numbers of shad are passed above each dam. Observations should be done regularly until the end of the spawning season. The use of radio-tagged adult shad from a separate Study Request will aid in this effort. An estimate of the total area used for spawning and an index of spawning activity should be recorded for each site.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Neither First Light or TransCanada propose any studies to meet this need. Estimated cost for the study is expected to be moderate (up to \$40,000) for each owner, with the majority of costs associated with fieldwork labor.

Study Request 4: Downstream American Eel Passage Assessment at Turners Falls Dam and Northfield Mountain (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

The goal of this study is to determine the impact of two hydroelectric projects on the outmigration of silver eels in the Connecticut River. Entrainment of eels at the Northfield Mountain Pumped Storage Station (NFMPS) removes eels from the river, effectively extirpating them from the population. Entrainment at the conventional turbines at Station 1 and Cabot Station of the Turners Falls Project can result in mortality or injury. It is important to understand the passage routes at each project and the potential for mortality to assess alternative management options to increase survival.

The objectives of this study are:

1. Quantify the movement rates (including delays) and relative proportion of eels passing via various routes at the projects; i.e. for NFMPS, the proportion entrained into the intake; for Turners Falls Dam, the proportion entrained into the power canal and spilled via bascule and taintor gates; for the Cabot Canal, proportion of fish passing via spillways, turbines, and the downstream bypass.
2. Evaluate instantaneous and latent mortality and injury of eels passed via the Turners Falls Dam routes, including bascule and taintor gates, spillways, turbines, and the downstream bypass.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...”

Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to downstream passage of American eel, the Service’s goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requester is a resource agency.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Existing Information

The PAD contains information on the biology, life history, and regulatory status of American eel. It also discusses 2-D and 3-D telemetry studies that were conducted at Cabot Station in 1996, 1997, 2002 and 2003. Results of those studies indicate that a significant proportion of eels entering the Cabot forebay become entrained (90% in 2002, 100% in 2003; Brown 2005, Brown et al. 2009). The PAD notes that the study done in 2003 determined that 15 of the 29 test eels were detected at the Hadley Falls Station. However, that study was not designed to assess turbine mortality.

To date, no directed studies of eel mortality at Cabot Station or eel entrainment or mortality at either Station 1 or the NFMPS facility have been conducted. These information gaps need to be filled so resource agencies can assess the relative and cumulative impact of project operations on outmigrating eels and develop adequate passage and protection measures to meet management goals and objectives.

We also note that within the past seven years, the Service has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability (CESAR). On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made prior to any new licenses are issued for the projects.

Nexus to Project Operations and Effects

The Turners Falls Project operates as a peaking facility, except during periods when inflow exceeds the hydraulic capacity of Cabot Station and Station 1. Silver eels outmigrate during the mid- summer through late fall, a time of year when flows are generally near the maximum operating capacity of the stations. Therefore, the project would be expected to spill infrequently during the silver eel outmigration beyond the nominal amount required in the bypass reach.

Racks at Cabot Station, Station 1, and NFMPS facility are not designed to protect eels from entrainment. At Cabot, the racks have one-inch clear spacing on the top 11-feet, with five-inch clear spacing on the bottom 20 feet of racks. The approach velocity at the racks is approximately 2.0 feet per second at maximum hydraulic capacity. At Station 1, the racks have 2.6-inch clear spacing and an approach velocity of 1.2 feet per second. Eels can readily pass through a 2.6-inch clear space. NFMPS has 48-foot-deep trashracks with six-inch clear spacing over the intake and an approach velocity of 3.5 feet per second at full pumping capacity (15,000 cfs).

As mentioned above, previous studies conducted at Cabot Station documented eel entrainment. Cabot Station has existing downstream passage facilities designed for anadromous species, but studies have documented few eels utilizing the surface bypass (likely because Cabot has a relatively deep, wide intake area). Station 1 has no passage and protection facilities. NFMPS has a seasonally-deployed barrier net to minimize entrainment of Atlantic salmon smolts, but it is only operated from April through June 15 annually. While no studies have been conducted at Station 1 or NFMPS facility, the rack spacing is wide enough to allow for entrainment.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Methodology Consistent with Accepted Practice

In order to understand the movements of outmigrating silver eels as they relate to operations at the Northfield Mountain Pump Storage Facility, Station 1, and Cabot Station, radio telemetry technology should be utilized. Radio telemetry is an accepted technology that has been used for a number of studies associated with hydropower projects, including at the Muddy Run Project (FERC No. 2355).

Studies should be designed to investigate route selection (i.e., entrainment vs. spill) independently from estimation of mortality/injury, because these metrics require different telemetric methodologies. Studies also will likely benefit from data from several seasons (especially route selection studies, which may be more significantly affected by environmental conditions during a given season than mortality/injury studies). It is also envisioned that results from route selection studies can guide design of turbine mortality studies. Therefore, it is proposed, at a minimum, that route selection studies be conducted in multiple years, but mortality/injury studies may be conducted after the first year of route selection studies have been completed.

1. Objective 1: Route Selection

This study will involve systematic releases of radio-tagged silver phase eels at strategic points above areas of interest, to assess general routes of passage (i.e., via spill, bypass, or turbines). Active downstream migrants should be collected within-basin if possible (i.e., Cabot or Holyoke bypass samplers), but fish sourced from out of basin may be acceptable to meet sample size demands. Experimental fish must meet morphometric (e.g. eye diameter relative to body size) criteria to ensure they are migrant silver phase. Collections should be made within the migratory season (late Aug to mid Oct), and eels should be tagged and released within 7 days of collection.

NFMPS Route Selection Study:

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Eels will be released at least 5 km upstream of the NFMPS project; releases should be timed so that there is a significant probability that migrating eels will encounter NFMPS during the pumping stage. Radio telemetry antennas will be strategically placed to determine times eels are present within the river reach in the vicinity of the NFMPS intakes, within the intakes themselves, and whether they are entrained into the upper reservoir.

Turners Falls Dam Route Selection Study:

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Groups of eels should be released during spill and non-spill periods if possible. Tagged eels will be released at least 3 km upstream of the Turners Falls dam but several km below the intake to NFMPS. Telemetry receivers and antennas will be located above and below the dam to assess passage via the following potential routes: entrainment into power canal; passage via spill over the bascule gates; passage via spill through the taintor gates.

Eels from the NFMPS route study not entrained into the NFMPS intake and migrating to the Turners Falls Dam may be used to supplement (but not serve in lieu of) these release groups.

Turners Falls Project – Canal Route Selection Study:

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Groups of eels should be released during periods of low, moderate, and high generation conditions if possible.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Eels will be released in the upper canal (ideally just downstream of the Gatehouse), and allowed to volitionally descend through the canal. Telemetry receivers and antennas will be located within the canal, bypass, channel, and mainstem below Cabot Station to assess passage via the following potential routes: Spillway Fishway attraction water intake (if operational); Station 1 turbines; Cabot Station spillway; Cabot Station bypass; Cabot Station turbines

Eels from the NFMPS and Turners Falls Dam Route Studies not entrained into the NFMPS intake and migrating into the Turners Falls Canal may be used to supplement (but not serve in lieu of) these release groups.

Mobile tracking (i.e., via boat) in river reaches between release sites and several km downstream of Cabot Station will be performed at regular intervals during and after releases to confirm routes and fates of passed fish, or fish lost to follow-up.

Movement rates (time between release and passage) of eels passing the projects by various routes will also be quantified.

The route selection portion of this study should occur in both study years.

2. Objective 2: Spill, Bypass, and Turbine Mortality/Injury Studies

Spill, bypass, and turbine mortality will be assessed using a radio-telemetric balloon tag method. A minimum number of 50 tagged eels (e.g., 5 separate groups of approximately 10 eels each) will be required at each location (dam bascule gate, dam taintor gate, Cabot Station spillway, Cabot Station bypass, Station 1 and Cabot Station) to maximize the data return. Turbine mortality studies are not required at NFMPS because it is assumed that all entrained fish (including eels) are lost to the Connecticut River system.

For spill mortality sites (dam bascule gate, dam taintor gate, Cabot spillway, Cabot Station bypass), tagged eels will be injected or released into spill flow at points where water velocity exceeds 10 ft/sec, to minimize the possibility of eels swimming upstream into the headpond or canal. Passed balloon-tagged eels will be recovered below areas of spill and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.

For turbine mortality sites (Station 1 and Cabot Station), tagged eels will be injected into intakes of units operating at or near full generation at points where intake water velocity exceeds 10 ft/sec, to minimize the possibility of eels swimming back upstream through the intakes. Passed balloon-tagged eels will be recovered in the tailrace and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.

Mobile tracking (i.e., via boat) in river reaches between release sites and several km downstream of Cabot Station will be performed at regular intervals after releases to confirm routes and fates of passed fish, or fish lost to follow-up.

The turbine mortality component of the study should occur in Study Year 2.

Data analyses of route selection and turbine mortality (instantaneous and latent) will follow standard methodology.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the downstream eel passage study would be moderate to high; silver eels would need to be collected, tagged, and released in several locations over the course of the migration season. Antennas and receivers would need to be installed at the intakes to all stations as well as at the Turners Falls dam spillway and Cabot Station bypass, and monitored regularly. Data would need to be retrieved periodically, then analyzed. A multi-site route selection study conducted by the USGS Conte Lab on the Shetucket River in Connecticut cost approximately \$75,000 for the first year of study. Cost are estimated at \$100,000 per year for the Route Selection studies and \$75,000 per year for the Spill, Bypass, and Turbine Mortality/Injury Studies.

In the PAD, the applicant has identified the need to assess issues related to downstream passage for American eels at the project, but indicates that it intends to rely on information from previously conducted studies and ongoing studies. The Service is not aware of any previously conducted or ongoing studies related to downstream eel passage.

Study Request 5: Impacts of the Turners Falls and Northfield Mountain Pumped Storage Project Operations on Tributary and Backwater Area Access and Habitats (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

One goal of this study is to determine if water level fluctuations from the Turners Falls and Northfield Mountain Pumped Storage projects result in a barrier(s) to fish movement in and out of tributaries and backwaters to the impoundments and riverine reaches below dams.

A second goal is to determine if water level fluctuations in the Turners Falls and Northfield Mountain Pumped Storage project impoundments impact water levels, available fish habitat and water quality in tributaries and backwaters to the impoundments and riverine reaches

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

below dams, and if impacts are found, to ascertain how spatially far reaching they are and develop mitigation measures.

Results of this study may also be used to help determine the adequacy of existing downstream minimum flow requirements.

Specific objectives include:

1) Conduct a field study of tributaries and backwaters, including water velocity and habitat data where appropriate, to evaluate potential impacts of impoundment fluctuation on fish access to tributaries and backwater areas. The study should also evaluate if changes in impoundment fluctuation range would mitigate for any identified impacts and if other mitigative measures would improve access.

2) Conduct a field study to examine potential impacts of impoundment fluctuations on water levels, available habitat and water quality in tributaries and backwaters. The evaluation should also evaluate if changes in impoundment fluctuation range would mitigate for identified impacts and if other mitigative measures would lessen these impacts.

Resource Management Goals

This requested study will help promote tributary and backwater access and protect valuable fish habitat and maintain appropriate water quality conditions for diadromous and riverine fish species in project-affected areas. Maintaining connectivity between the mainstem of the Connecticut River and tributaries and backwaters is vital to the fish populations in these systems, as many fish species utilize these areas for spawning, rearing, refuge, and feeding.

Public Interest

The requestor are natural resource agency.

Existing Information

To our knowledge, limited information exists related to this requested study.

Nexus to Project Operations and Effects

Project operations have the potential to impact fish species life history requirements, biological interactions, and habitat quantity and quality. For example, water level changes due to project operations could create conditions that could impede free movement of fish between tributaries/backwaters and the mainstem of the Connecticut River, thus limiting access to spawning habitat and/or growth opportunities. Additionally, water level changes could also alter tributary and backwater fish habitat quality, quantity, and also water quality, thus decreasing productivity and available habitat.

Methodology Consistent with Accepted Practice

Common tools to evaluate water level impacts would be used including: bathymetric mapping, substrate, depth and velocity measurements, and water quality information (dissolved oxygen, temperature, turbidity, and pH). Studies should be conducted throughout the year.

The study area for tributary and backwater fish sampling should cover all tributaries and backwaters within the project-affected areas of the Turners Falls and Northfield Mountain

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Pumped Storage projects. A second year of study may be required if first year data collection is limited due to environmental or other conditions, or if river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period.

Level of Effort/Cost, and Why Alternative Studies will not suffice

First Light does not propose any studies to meet this need. Estimated cost for the study is moderate.

Study Request 6: Northfield Mountain/Turners Falls Operations Impact on Sedimentation and Sediment Transport (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

Conduct hydraulic and sediment transport modeling of both the intake and discharge conditions (current and proposed) at Northfield Mountain. The results of the study should provide information sufficient to enable staff to understand current and proposed effects on water level fluctuations and relate to potential increase in sedimentation to the Connecticut River. Staff should be able to identify techniques that could be used to mitigate the effects of project operations or other mitigation techniques that could be developed to reduce riverbank erosion within the impoundment. In addition, an assessment of means to minimize the sediment load passing through the Turners Falls Canal during and after maintenance drawdowns should be conducted.

The specific objectives of this study are as follows:

- Assess hydraulic and sediment dynamics in the Connecticut River from Vernon Dam to Turners Falls Dam, the upper reservoir at Northfield Mountain, and downstream of the Turners Falls Dam.
- Identify management measures to minimize erosion and sedimentation.
- Determine areas of sediment deposition and beach formation in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas, recreational uses and effects on invasive species, if any. Habitat areas include but are not limited to coves (e.g. Barton Cove), back channels, islands, wetland habitats, shorelines, shoals, deep water areas and channels.
- Identify management measures to mitigate for substrate (habitat) impacts and recreational impacts in sediment-starved areas below the dam and sediment accumulation areas upstream of the dam.

Resource Management Goals

In order to meet the objectives of the federal Clean Water Act, MADEP adopted the Massachusetts Surface Water Quality Standards, 314 CMR 4.00. The Standards classify each body of water; designate the most sensitive uses to be enhanced, maintained and protected for

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

each class; prescribe minimum water quality criteria required to sustain the designated uses; and contain regulations necessary to achieve the designated uses and maintain existing water quality including, where appropriate, the prohibition of discharges into waters of the Commonwealth.

MADEP has designated the Connecticut River as a Class B river for its entire length in Massachusetts, 314 CMR 4.06(5). Class B rivers are assigned the designated uses of habitat for fish, other aquatic life and wildlife, and for primary and secondary contact recreation, 314 CMR 4.05(3)(b). Class B waters must also have consistently good aesthetic value and meet minimum criteria for numerous water quality indicators to achieve compliance with the standards set forth in the regulations. The anti-degradation provisions of 314 CMR 4.04 require protection of all existing and designated uses of water bodies, and maintenance of the level of water quality needed to protect those uses.

Public Interest

The requestor is a state natural resource agency.

Existing Information

The PAD provides a summary of the numerous studies that have been conducted to characterize streambank conditions of the Turners Falls Impoundment, to understand the causes of erosion, and to identify the most appropriate approaches for bank stabilization. The *Erosion Control Plan for the Turners Falls Pool of the Connecticut River* (Simons & Associates, Inc. dated June 15, 1999) was completed in order to comply with license articles 19 and 20, and contained a list of 20 priority streambank stabilization project sites. By the end of the current license, work at all sites will have been completed, although some require further repair work. The Erosion Control Plan (ECP) will need to be updated based on current science of fluvial geomorphology, and stakeholders will need to decide the direction additional future projects may take. The next Full River Reconnaissance is scheduled in 2013. Some of the goals and objectives of that effort is contained within this study request.

Implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) was begun in 2011 and is scheduled to end in 2014.

Nexus to Project Operations and Effects

Turners Falls and the Northfield Mountain Pumped Storage Project operate in a peaking mode, with allowable headpond fluctuations of up to 9 feet, with proposals to continue as such. It is proposed to evaluate increasing the volume of flow from the Northfield Mountain Pumped Storage Project through increased use of the upper reservoir which is expected to result in additional water level fluctuations. Upstream hydroelectric facilities also operate in a peaking mode of operation. Periodically, the upper reservoir at Northfield Mountain and the power canal at the Turners Falls dam need to be dewatered for maintenance purposes. Historically, both procedures have resulted in the discharge of large quantities of sediment.

Sediment from shoreline erosion and riverbank failure is one of the major contributors that negatively affect water quality and habitat by increasing the turbidity and sedimentation, smothering aquatic habitat. Repetitive water level fluctuations and flow alterations caused by hydroelectric peaking operations are known to be a major contributor to shoreline erosion.

The Proposed Massachusetts Year 2012 Integrated List of Waters shows two river segments, from the VT/NH state line to the Turners Falls dam (MA34-01 & MA34-02) impaired and considered a "Water Requiring a TMDL" due to "Other flow regime alterations", "Alteration in stream-side or littoral vegetative covers" and "PCB in Fish Tissue". In addition, the

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM
segment below the Turners Falls dam to the confluence with the Deerfield River (MA34-03) is impaired by these causes as well as total suspended solids.

Methodology Consistent with Accepted Practice

The MA Department of Environmental Protection recommends:

Assess hydraulic and sediment dynamics

- FirstLight continue implementing the Northfield Mountain Pumped Storage Project Sedimentation Management Plan over the full range of river flows and pumping/generating cycles. An unfulfilled task in the Plan is to develop a correlation over the full range of flow conditions between the overall suspended sediment transport through the entire cross section of the river compared to the continuous sampling at the single fixed location. Environmental Protection Agency approval of a Quality Assurance Project Plan is required for valid data acquisition.
- Provide data on the daily water level fluctuation changes from the past five years from stations listed in the PAD, and estimate fluctuations within Turners Pool assuming proposed operations and hydraulic conditions.
- Identify the most appropriate techniques for bank stabilization given the existing and proposed hydraulic conditions.

Determine areas of sediment deposition in the Project Area

- Field (2007) conducted a bathymetric study as part of his report. Use previous bathymetric data, if available (Field 2007 recommends putting additional effort into finding a bathymetric survey from 1913 that was partially shown in Reid 1990), and current bathymetric information to look at areas of sediment accumulation. Determine areas of sediment deposition in the Project Area and 1 km downstream of Cabot Station and describe habitat features of these areas. Habitat areas include but are not limited to coves (e.g., Barton Cove), back channels, islands, wetland habitats, shorelines, shoals, deep water areas and channels.
- Identify recreational uses and impacts in areas known to be impacted by accumulated sediment, such as Barton Cove.
- Identify invasive species (plant or animal) present in the reaches and determine if erosion and sedimentation in any way contributes to the establishment and/or proliferation of these species.
- Investigate the formation of beaches using remote sensing, LIDAR at low pool levels or some other mapping technique to understand the processes of beach deposition the distribution of beaches in the pool, the impact of beach deposition on habitat and species, and how can this be related to operation of NMPS.
- Evaluate management strategies to address the release of accumulated sediment through Northfield Mountain Project works during upper reservoir drawdown or dewatering activities. FirstLight should specifically evaluate the feasibility of the installation of a physical barrier across the bottom of the intake channel designed to prevent the migration of sediment during future drawdowns of the upper reservoir
- Evaluate management strategies to minimize flow fluctuations within Turners Pool including coordination with upstream users.
- Evaluate management strategies to minimize sediment released through spillway gates and the log sluice located near the bottom of the forebay adjacent to the Cabot Powerhouse during canal dewatering activities.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

- Identify a prioritized list of locations for bank stabilization projects in the Project Area
- Develop a map of land owned by FirstLight within 200 feet of the Connecticut River with an overlay of land use and vegetation cover. Provide land use options aimed at reducing bank erosion.

Management measures to change sediment flow below and above the dam.

- Any historic information of existing bed substrate material in the Turner's Falls headpond, bypass reach or downstream of the project should be collected and assembled. To the extent possible, the location of each sample should be made available on a map. The request for new data would stem from being able to make any valid comparison to changes in bed substrate at a given location, assuming the historic data exist.
- Identify measures that could be taken to mitigate impacts to recreational use, habitat, or invasive species from sedimentation.
- Identify measures that could be taken to change or mitigate sediment starved reaches below the Turners Falls dam.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Many erosion studies have already been conducted and the cost of expanding the scope of some should be reasonable. A Full River Reconnaissance under the *Erosion Control Plan for the Turners Falls Pool of the Connecticut River* (Simons & Associates, Inc. dated June 15, 1999) is scheduled for 2013 and should accomplish many of the objectives listed above.

Study Request 7: Model flows in the Northfield Mountain Pumped Storage Project discharge tailrace and Connecticut River 1 kilometer upstream and downstream of the discharge using two-dimensional Computational Fluid Dynamics (CFD) model techniques. (Docket Number p-2485)

Goals and Objectives

The goal of this study is to determine the potential impacts (both project-specific and cumulative) of the Northfield Mountain Pump Storage Project operations (pumping and generating) on the zone of passage for migratory fish near the Northfield Mountain turbine discharge/pump intake, on natural flow regimes in the area of the Connecticut River immediately upstream and downstream of the project, on the potential for entrainment during pumping operations, on the potential for creating flow reversals in Connecticut River during pumping cycles that may confuse migratory fish attempting to pass the project, and on bank erosion on both sides of the river in the vicinity of the tailrace.

Specific objectives of the study include:

- Develop a 2-dimensional CFD modeling capability for the area of the Northfield Mountain discharge and tailrace, along with the full width of the Connecticut River 1km upstream and 1 km downstream of the discharge.
- Model flow characteristics upstream and downstream of the project under existing project operations (pumping and generating) and at several representative river flow levels, as well as proposed operations such as those proposed in section 3.4.4 of the

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

PAD, and any other modifications under consideration, to assess potential impacts to fish and wildlife resources, recreational use, agricultural resources, and historical resources.

- Assess velocities at and in proximity to the Northfield Mountain intake/discharge structure, when pumping or generating and their potential to interfere with fish migration.
- Assess the potential for velocity barriers in the mainstem river resulting from pumping and generation flows at the project, alone or in combination with generation flows from the upstream Vernon Project.
- Assess potential for Northfield Mountain project operations to create undesirable attraction flows to the intake/discharge that may result in entrainment or delay of migratory fish.
- Assess the potential of a mainstem instream local flow reversal associated with pumping operations to impact migrating fish. The Connecticut River in the area of the Northfield Mountain tailrace has been said to flow upstream potentially confusing migratory fish keying in to flow as a directional aid to upstream or downstream migration, causing delay and additional "fish" energy expense and possible entrainment.
- Model and then evaluate flow characteristics under alternative project operations with potential measures to avoid, minimize, or mitigate impacts to fish and wildlife resources.
- Assess the potential for unnatural flows and eddies in the main-stem associated with pumping or generation at the Northfield Mountain Project to impact bank erosion and recreational use.

Resource Management Goals

The mission of the U.S. Fish and Wildlife Service (Service) is to work with others to protect, conserve and enhance fish, wildlife, plants and their habitats for the continuing benefit of the American public. Service trust resources include wetlands, endangered species, and migratory species, all of which have been documented to occur in the project area. The Service is also working with a number of federal, state, local, non-governmental organizations, and the public to restore and enhance trust resources in the Connecticut River Basin through comprehensive management plans and cooperative agreements. Instream flow is an important riverine habitat characteristic that can have a great impact on aquatic habitat for fish, wildlife, and plants. Flow is an important directional guidance cue for instream navigation and attraction to fishway entrances for migratory fish.

Public Interest

The requestor is a federal natural resource agency.

Existing Information

No project specific information exists that will allow for a comprehensive assessment of existing project operations (pumping and generating flows) on Connecticut River flows and on fish and aquatic organisms in the project area upstream and downstream of the project in the Connecticut River. Preliminary results from an ongoing study of radio-tagged American

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

shad by the USFWS and USGS Conte lab indicate that shad are exposed to the intakes and some individuals spend substantial amounts of time in the vicinity of the intakes. The PAD does not contain any information or tool that will allow for predictions of impacts of alternative project operations, or potential mitigation measures to protect or enhance aquatic fish and wildlife resources.

As part of Field (2007; see appendix 4), a “Connecticut River Hydraulic Analysis – Vernon Dam to Turners Falls Dam” was completed by Woodlot Alternatives in July 2007. For this analysis, a 2-dimensional flow model was developed for the entire Turners Falls impoundment. This study was geared towards looking at shear stresses from high-flow events, and did not focus in detail around the tailrace or examine how pumping and generation may affect flows in the vicinity of the tailrace under a variety of flows.

As a result of the hydraulic analysis, Field (2007) on page 20 states that “While erosion does occur where high flow velocities and shear stresses approach near the bank, significant amounts of erosion also occur where flow velocities near the bank are low.” No specific examination was done in the report on the ± 1 km area near the tailrace and existing erosion sites. Banks immediately upstream and downstream and across river have all required bank stabilization projects over the last 15 years, in some cases needing several repairs.

Nexus to Project Operations and Effects

Existing project operations have a direct impact on instream flow and aquatic habitat in the pump/discharge area of the Connecticut River. The PAD in section 3.2.2 says that the velocity at the trash racks when operating at full capacity is 20,000 cfs and maximum pumping conditions are 15,200 cfs. Annual flow duration curves shown for below the Vernon Dam submitted in the PAD section 4.3.1.2 (for years 1944-1973; recent and near project flows are not available; see p. 459) indicate that river flows are $\leq 20,000$ cfs more than 85% of the time. Flows released from the project must therefore influence flow patterns and velocities in the Connecticut River, particularly at flows below some unknown threshold level.

Recreational users of the Connecticut River in the Turners Falls impoundment have anecdotally described flow reversals in the mainstem river. Discharges from the project could potentially be larger than river flows or at least act like a major tributary to the Connecticut River. Project flows may influence the availability and extent of upstream and downstream migration zones, or may confuse fish and delay migration. Project flows may also impact stream banks in ways that natural river flow (or flows affected by upstream hydropower facilities) does not, and may also impact recreational use of the river.

Proposed Methodology

CFD modeling is consistent with generally accepted practice, and has been used to assess proposed modifications to the Holyoke Dam fish passage facilities, upstream of the intakes and downstream of the dam, as well as at hydroelectric projects on the Susquehanna River to assess existing and proposed project operations, and develop mitigation measures for fish and wildlife resources.

Level of Effort/Cost, and Why Alternative Studies will not suffice

This study will require a detailed elevation map of the study area upstream and downstream of the Northfield Mountain project. Information already exists in historic construction files for the project, the hydraulic analysis included in Appendix 4 of Field (2007), and possibly in conjunction with work done after the 2010 maintenance procedures that resulted a portion of the river being dredged after a large sediment dump) that are in the possession of the applicant. Additional elevation data will likely need to be collected in the field using standard survey techniques. Elevation data will then need to be entered into a CFD modeling program.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

The CFD computer program will need to simulate existing project operations that include all potential variations of pumping and generating, and static operation. No project specific instream flow analysis tool has been developed for the Northfield Mountain project that will allow for assessment of existing operations and alternative operational impacts on instream flow and aquatic habitat for fish and wildlife resources. The computer model, once built, can be used to simulate flow conditions in the vicinity of the project during migratory fish passage and can be used together with behavior studies (i.e., telemetry studies and entrainment studies requested herein) to assess the impacts of varying project operations or potential mitigation operations and measures on fish migration and aquatic habitat. We know of no other tool that will provide for these types of assessments. Cost is expected to be moderate to high.

Study Request 8: Entrainment of Migratory and Riverine Fish from the Connecticut River into the Northfield Mountain Pump Storage Project. (Docket Number p-2485)

Goals and Objectives

The goal of the study is to determine the impact of Northfield Mountain Pump Storage Project (NFMPS) during the pumping cycle on entrainment of juvenile American shad, adult shad, adult American eel, and riverine fish, including early life stages.

The objective of the study is to quantify the number of resident and migratory fishes entrained at the NFMPS intake on an annual basis in order to evaluate potential impacts to riverine fish populations in the Turners Falls pool and diadromous fish migrants moving through the project area. This will be accomplished through a combination of hydroacoustic monitoring and netting using various gear types to quantify and identify species of different life stages.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually. (Table 1)
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

Based on the CRASC plan, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...”

Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Specific to resident riverine and migratory fish entrainment, the Service’s goals are:

1. Minimize current and potential negative project operation effects such as turbine entrainment that could hinder management goals and objectives.
2. Minimize project-related sources of mortality to resident and migratory fishes in order to restore natural food web interactions and ecosystem functions and values.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Limited project-specific information exists regarding entrainment of fish and aquatic organisms at the NFMPS. As part of a Memorandum of Agreement between then-owner Northeast Utilities Service Company (NUSCO) and regulatory agencies (including the Service), NUSCO conducted studies to determine the impact of NFMPS on anadromous fishes, including Atlantic salmon, American shad, and blueback herring. Results of a pilot study conducted in the fall of 1990 indicated that trap netting at the intake was ineffective at collecting fish. Gill netting and boat-shocking did result in collection of some juvenile shad, but further refinement in both methods was recommended to improve effectiveness. A total of

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

78 fish were collected at the intake (77 of which were American shad) by gill netting and 11 shad were collected by boat electrofishing. Hydroacoustic monitoring was deemed an effective method for monitoring entrained fish during pumpback operation. Hydroacoustic sampling over a two-week period (September 12-27, 1990) produced hourly entrainment estimates that cumulatively equaled 14,816 fish.

Based on the results of the pilot study, NUSCO developed a two-year plan to quantitatively determine the number of shad and salmon entrained at NFMPS station. In 1992, an entrainment study targeting juvenile American shad life stages was conducted in the lower (mainstem river) and upper reservoirs of NMPS. The study used several gear types to quantify egg through juvenile shad densities in different areas. Entrained juveniles were sampled using an upper reservoir net. Pumping operations were modified to only run three (77% of sample time) and sometimes two (23% of sample time) of the station's four units during the study and effort was limited to a total of 80 hours over a period spanning 9 August through 27 October (80 days). An estimated total of 1,175,900 shad eggs, 2,744,000 yolk-sac larvae, 10,525,600 post yolk-sac larvae, and 37,260 juveniles were reported entrained.

There are no reliable data on the timing, magnitude and duration of entrainment of larval riverine fishes in the NFMPS area. Unlike anadromous shad and river herring, riverine species occurrence and susceptibility relative to space and time exposure windows to NFMPS pumping, are undocumented. The complete lack of any long-term fish population monitoring data for riverine species in the Turners Falls impoundment leaves questions unanswered on the types and extent of impacts to these populations that may be linked to the near daily cycling of river water up and down through the NFMPS operations system. As a starting point, it is necessary to obtain baseline data on project operation impacts for all species potentially impacted by NFMPS. An additional study request seeks to obtain a more accurate documentation of all fish species inhabiting or utilizing the Turners Falls impoundment.

Nexus to Project Operations and Effects

Entrainment of fish and aquatic organisms associated with water withdrawal and hydroelectric operations has been documented to result in injury or death of entrained organisms. Migratory and resident fish pass through the project area directly in front of the pump intakes. These organisms may be entrained and thus exposed to passage through the project pumps and reservoir supply tubes. How far from the intake these species and life stages may be drawn into the intake on a pumping cycle or how susceptible they are to the repeated daily cycles of pumping and discharge, and how these factors vary in relation to habitat and river conditions are unknown. Survival of fish subjected to entrainment on the pumping cycle is unknown, but regardless of whether fish survive the pumping process, they are lost to the Connecticut River system. Depending on the species, life stages, and numbers entrained, this loss could impact the ecosystem productivity of the Turners Falls pool and may hinder restoration goals for diadromous fishes.

Previous entrainment studies have been conducted at the project. Those studies, which were done 20 years ago, documented entrainment of American shad and Atlantic salmon at the project, including over 13 million yolk sac and post-yolk sac larvae of American shad. This level of entrainment is cause for concern, not only due to the resultant loss of potential adult returns, but for the important role early life history phases and juveniles play in their ecological contributions to the river system (e.g., trophic interactions).

No entrainment studies for other species of fish have been conducted at the project. The unknown extent of other riverine species ichthyoplankton entrained by the NFMPS requires evaluation. Studies conducted in 1969 and 1970 at the Muddy Run Pumped Storage Station

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

documented significant entrainment of eggs and larval fish. In June and July of 1970, 5.3 million eggs and 56.6 million larvae were entrained (Snyder 1975). Muddy Run and NFMPS are of a similar size and both use a river as the lower reservoir. It is anticipated that a considerable number of eggs and larvae will be entrained by the NFMPS.

Since the previous studies were conducted, operations at the NFMPS facility have changed (e.g., the project increased the efficiency of its turbines, and raised the pumping capacity from 12,000 cfs up to 15,000 cfs), as have river conditions (e.g., Vermont Yankee has increased its thermal discharge and the Vernon Project has increased its station capacity). Further, the PAD indicates that FirstLight will evaluate the feasibility of utilizing an additional 3,009 acre-feet of storage capacity to generate an additional 1,990 MWhs (this represents a 23% increase over existing storage and stored generation levels). While not specified in the PAD, increasing storage and generation would mean longer periods of both pumping and generation at NFMPS. In addition, anticipated improvements in fish passage at the Turners Falls Project will result in increased juvenile production above the NFMPS. These factors, individually or cumulatively, could increase the potential for entrainment at NFMPS station.

Methodology Consistent with Accepted Practice

Previous studies used varying methodologies for determining entrainment. The 1990 study concluded that hydroacoustic monitoring at the intake was a viable method for determining entrainment of later life stages, but does not allow for identification of the species being entrained. While trap netting was ineffective at collecting fish near the intake, gill netting and boat shocking did capture some fish. Both may prove to be viable sampling methods; however it is likely that additional testing and gear refinement will be necessary.

The 1992 study used nets at the pump discharge location into the upper reservoir to collect entrained fish. Testing showed that this method was only 10% efficient. Plankton netting in the nearfield area of intake was used to estimate entrainment of ichthyofauna. It is likely that a combination of methods would provide the most reliable results (e.g., hydroacoustic monitoring at the racks during pumpback operations, variable gear sampling in the vicinity of the intake immediately prior to initiation of pumpback operations to determine species composition, and plankton netting in the nearfield area of the intake to obtain information on entrainment of ichthyofauna). As these methodologies have previously been utilized at the site, they are consistent with accepted practice.

Although a previous entrainment study was conducted, the Service believes it should be repeated, using a modified study design. The 1992 study only collected a total of 330 juvenile shad over a three-month period (resulting in an overall estimate of 37,260 juveniles entrained, after accounting for poor net efficiency); whereas the hydroacoustic study conducted in 1990 estimated nearly 15,000 fish in 15 days (while these fish were not identified, 77 of the 78 fish collected at the intake during the study were juvenile shad). It also should be noted that in the 1992 study, juvenile shad were collected on the first day of sampling, indicating that the sampling did not begin early enough, which would mean the results are an underestimate of the number of juvenile shad that were actually entrained. In 1990, 27,908 adult shad passed the Turners Falls gatehouse, while in 1992 over 60,000 shad passed gatehouse. The fact that the numbers entrained were so variable between study years argues for repeating the study, using a combination of previously-used methodologies.

The study will require deployment of at least five hydroacoustic transducers (one per rack face and one offshore). These transducers would be operated during every pumping cycle from April 15 through May 14 to assess riverine fish entrainment, from May 15 through July 15 for spent adult shad, and from July 16 through November 30 for entrainment of adult silver

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

eels, juvenile American shad, and riverine fishes. Concurrent field sub-sampling at the intake to determine species composition would need to occur.

Sampling for planktonic fish larvae should capture early spring spawning species (white suckers) through later season centrarchid species (bass and sunfish). Active plankton trawl surveys should utilize a sampling design that adequately captures temporal and spatial changes in water pumping cycle (i.e., early start-up is local water, later cycle pumping is drawn in from both upstream and downstream habitat areas).

Level of Effort/Cost, and Why Alternative Studies will not suffice

We know of no other tool that will provide for this type of assessments for all fish species and organisms that may pass through the project. Cost and effort are expected to be high.

The applicant did not propose any studies to meet this need in the PAD.

Study Request 9: Study of shoreline erosion caused by Northfield Mountain Pumped Storage (NMPS) operations (Docket Number p-2485)

Development of the current configuration of the Northfield Mountain Pumped Storage project included raising the dam height at Turners Falls by 5.9 feet in 1970 in preparation for NMPS operations. Operations began in 1972; since then all project operations have operated under this raised dam environment. The operation of NMPS causes alterations to the river as a direct feature of plant functionality. The alterations include: 1) daily fluctuating pond levels which at times in some places can exceed six feet (the license allows fluctuations up to 9 feet measured at an undisclosed location near and upstream of the Turners Falls dam), 2) altered flow and velocity profiles of river and 3) changes to the downstream hydrograph. Elevation data of the head pond in Appendix E of the PAD indicate that stage changes of 2 to 3 feet during the summer of 2012 were not uncommon. The additional 5.9 foot elevation increase in the headpond resulted in motorized boat traffic becoming more popular and makes the use of larger boats more possible. The presence of motorized recreational boats increases wake energy that can accelerate bank erosion rates.

Raising the level of the headpond can saturate bank soils. These same soils can quickly become dewatered when the headpond is lowered. Repeated saturation and dewatering of banks can lead to bank instability which in turn can lead to bank failure and eroded material entering the river. See Field (2007) for an extended discussion on bank erosion and failure mechanics. Elevated levels of turbidity and suspended solids in the water column can

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

diminish rearing and migratory habitat for fish. When too much fine grain material is deposited on channel bed substrates, particularly those substrates used for spawning, spawning success of resident and migratory fish is compromised, potentially reducing recruitment and carrying capacity.

Goals and Objectives

The goals of this study request would be to determine the environmental effects of the presence and operation of the licensed facilities on river bank stability, shoreline habitat, agricultural farmland, wetland resources, bed substrate, and water quality in the Turners Falls impoundment. We recognize that data from other studies will be made available and we think that the data from these other studies could be used to help meet the objectives of this study request.

Objectives of the study include the following

1. Calculate the total volume of eroded material, calculate resulting nutrient loading of eroded material, and document and describe the three dimensional changes to the bank, including lateral bank recession, changes to bank slope, and the presence and subsequent inundation of pre-project beaches and shoreline since the Turners Falls Dam was raised and the Northfield Mountain Pumped Storage facility came on-line.
2. Document and describe the changes to banks upstream and downstream of riverbank restoration projects, including bank recession.
3. Identify the changes that have occurred to bed substrate as a result of fine grain material being eroded from the banks and being deposited on the channel bed.

Relevant Resource Management Goals and Public Interest Considerations

Our management goal is to ensure high quality habitat for migratory diadromous fish. Shortnose sturgeon, American shad and American eel all require suitable spawning, rearing, migratory and foraging habitat. Eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turner's Falls headpond, the bypass reach and downstream of the Turner's Falls project reduces the quality of habitat for these species. Elevated levels of suspended sediment are associated with a diminution in water quality which also affects the quality of habitat encountered by trust resource species. In addition to habitat effects, soil erosion contributes to nutrient loading. In 2001, the U.S. EPA 2001 approved New York and Connecticut's Long Island Sound (LIS) dissolved oxygen TMDL. As a result, the New England Interstate Water Pollution Control Commission (NEIWPCC) established the Connecticut River Workgroup and the Connecticut River Nitrogen Project. This project is a cooperative effort involving staff from NEIWPCC, the states of Connecticut, Massachusetts, New Hampshire, and Vermont, and EPA's Region 1 and Long Island Sound (LIS) offices. All are working together to develop scientifically-defensible nitrogen load allocations, as well as an implementation strategy, for the Connecticut River Basin in Massachusetts, New Hampshire, and Vermont, which are consistent with TMDL allocations established for LIS. Since its inception, the Connecticut River Workgroup has participated in a number of projects to better understand nitrogen loading, transport, and reductions in erosion.

Public Interest

The National Marine Fisheries Service is a Federal agency.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Existing Information and Need for Additional Information

The PAD makes reference to several studies in section 4.2.4 including the Erosion Control Plan (Simons & Associates, 1999), previous Full River Reconnaissance studies (1998, 2001 – maps but no report generated, 2004, and 2008), Field Geology Services' 2007 fluvial geomorphic investigation of the Turners Fall headpond, and 2012 investigations by Simons & Associates.

Field Geology Services' 2007 investigation provided several good recommendations for future work in section 9.3 of his report which, if implemented, could provide for: a) an improved understanding of the causes of erosion; b) more accurate monitoring of erosion; and c) more successful bank stabilization efforts. This document is a good point of reference. The Simons & Associates' (2012) documents are qualitative and based on several unstated assumptions that may not be valid. Full River Reconnaissance efforts have been undertaken using varying methodologies, making for difficult comparisons from one report to the other.

We believe that these existing studies do have data that can be useful if certain new analyses are undertaken. These analyses of existing data would help fill in our gaps of understanding of bank erosion in the Turners Fall headpond. We are also asking for some additional field collected data. With the existing information, it should be possible to better display what changes have occurred to streambanks over time. Current Geographic Information System (GIS) software allows for various types of data to be assembled into a map and into a database such that change over time analysis can be conducted fairly easily. The change over time analysis is a critical analysis that is needed, and was already started under Field (2007).

Photos that have been taken at or near the same location but at different times exist. For example, the last three Full River Reconnaissance efforts have included continuous videotaping of the river banks with locational information. With these data, "snapshots" of the bank at various locations could be extracted and compared over time. Field (2007) photo locations could be re-shot as well. This existing information should be presented such that it is easy to discern where the photo was taken and what changes have occurred over time. A comparison of the bank every 100 ft could be compared over the years.

Historic aerial photography for the Turners Fall headpond should be gathered and analyzed. Examples of good photographic datasets include the Field 2007 appendices and 1929 aerials. The location of the shoreline over time should be noted such that it is easy to discern where bank retreat has been most severe and where the river has been relatively stable since the earliest aerial photograph was taken.

Very little turbidity data for the Turner's Falls headpond, the bypass reach or stretches of the Connecticut River downstream of the Turner's Fall project exist. Thus far, implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) has yielded few results, and many technological difficulties (see *2012 Sediment Management Plan – 2012 Summary of Annual Monitoring* dated November 30, 2012). Suspended sediment monitoring equipment is installed at the Route 10 Bridge upstream of the project and inside the powerhouse, theoretically taking readings representative of pumping and discharging through the turbines. An analysis of how turbidity might change relative to rapidly changing headpond levels would be very useful information.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Project Nexus

The construction of the NMPS project was contingent upon the Turner's Falls project raising the dam crest elevation by 5.9 feet. The NMPS project operations rely on the Turner's Falls headpond as the source of water to be pumped and to be discharged into. The importance of this river reach to the NMPS operation is made clear by Firstlight's reference to this portion of the river as the "lower reservoir." Daily pumping and discharging changes the ponded elevation of the Connecticut River which in turn leads to bank material that repeatedly becomes saturated and then dewatered. Weakened bank material can then become eroded and the fine grain material from the banks can enter the water column and be transported in suspension in the river and eventually settle onto bed material. The raising of the Turner's Falls headpond also made recreational boating more popular, including the introduction of large, high-horsepower powerboats that were not previously present. Because of the fluctuating water levels, boat wakes impact the shoreline to a much greater extent than would occur if levels were more constant, thus exacerbating both the effects of the wakes and the fluctuating levels. For these reasons, erosion caused or contributed by NMPS project operation can negatively affect spawning, rearing and migratory habitat for trust species and the endangered shortnose sturgeon. The requested study will help inform the Commission when contemplating mitigation measures and or operational modifications.

Proposed Methodology

1. This study should determine the net soil loss in cubic yards between 1970 and the present; a density estimate of the eroded material should also be provided. Provide an analysis of where the greatest loss has occurred, location of proximity to the tailrace, soil type, riparian land use, and vegetative cover in that area. Calculate nutrient loadings (nitrogen and phosphorus compounds) to the river system based on soil loss.
Obtain copies of the original survey plans for the project, and complete a new survey using the same landmarks used previously. The Field (2007) report states on page 11 that the original survey plans of the river are still retained by Ainsworth and Associates, Inc. of Greenfield MA. Use pre-operation aerial photos and current aerial photos to complete a 10-foot topographic map of the section of river between Turners Falls Dam and Vernon Dam and the 200-foot buffer regulated under the Massachusetts Rivers Protection Act. The Field (2007) report on page 11 states that Eastern Topographics, Inc. determined that sufficient information is known about the 1961 aerial photos (e.g., height of airplane) to create a 10-foot topographic map of that time period, and that 1961 aerial photos could be accurately overlaid with recent aerial photos. Field (2007) states that this analysis would enable a more reliable determination of small-scale shifts in channel position and changes in bank height that may have resulted from the erosion of a low bench that previously existed along portions of the river. Among other things, create a single map showing areas of erosion and deposition, and also overlay the Field report's hydraulic modeling analysis of the river channel.
2. With respect to the January 22, 2013 submittal from FirstLight to FERC regarding its long term monitoring transects in the Turners Fall impoundment, we ask that any data errors (as discussed in Field, 2007) and problems that have occurred over the years at each site be mentioned. We also ask that that an analysis for each cross section extending to the top of the bank and including a portion of the floodplain be provided.
3. Take the information presented in Figure 4.2.3-1 "Soils in the vicinity of Turners Falls and Northfield Mountain projects" in the PAD and convert from 63 categories to just a few that are defined in a key that will allow readers to understand which soils are easily erodible, which aren't, and where there is bedrock along the banks.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

4. Complete detailed surficial mapping (topographic map or LIDAR) to identify the various geomorphic surfaces, height of benches/terraces above the river level, and types of sediments underlying the surfaces. This will allow one to determine how erosion varies with geomorphic conditions. One could then normalize the amount of erosion to a specific type of bank material/geomorphic surface/terrace.
5. Another information request covers the range of daily water level fluctuations. In this study request, we ask for an analysis on the degree to which boat wakes increase that fluctuation range. The task would be to observe boat wakes under a range of boat sizes and flow rates on the river. We recommend the 2007 Field report recommendation which states, "A more thorough study of boat waves is merited to better document how many boats use the Turners Falls Pool, how fast they travel, the type and size of waves they produce, and their impact on shoreline erosion."

A component of this study request is not necessarily for new data, but for existing data to be presented in a more clear, coherent and comprehensive manner. All existing photographs of banks that have been collected either by Firstlight, on behalf of Firstlight or on behalf of the FRCOG Streambank Erosion Committee should be georeferenced in such a way such that it is easy to discern where the photograph was taken and the date should be easily discernible as well. These photos should be presented in a manner that makes it easy to visually see how a particular section of bank has changed over time. Providing geographic context for photographic data of river banks and making these photos comparable over time should be standard practice. The 2007 Field report contains the following recommendation on page 47: "An attempt should be made to overlay the 1961 aerial photographs with a current flight and to create a topographic map from the 1961 flight. The feasibility of this effort has been confirmed by Eastern Topographics, Inc. This effort will identify the previous extent of the low bench and identify areas of the most significant bank recession the past 45 years." Given that this statement was written in 2007, we request that that the analysis is extended to current conditions.

Given the complexity of this study request and the expertise necessary to implement it, we request that the resources agencies be involved with the selection of the hired consultant.

Level of Effort and Cost

The level of effort to compile existing information and to make the data available in a map and searching for existing bed substrate material data should not take more than a few days. The level of effort for the bed sampling work will vary based upon how much existing historic information exists. Much of the effort of this study request is essentially office work that compiles and better presents existing data. While an estimate on the amount of field time required is difficult to make, we estimate that up to two weeks of field work could be required and some of the data collection could be done while other field studies are occurring.

Study Request 10: Shad Population Model for the Connecticut River (Docket Number p-1889) (Docket Number p-2485)

Develop an American shad annual step, mathematical simulation population model for the Connecticut River to quantify how project operations and potential restoration/mitigation measures impact the population of shad in the Connecticut River.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Goals and Objectives

The goal of the model is to assess impacts of both upstream and downstream passage at each of the Connecticut River projects and potential management options for increasing returns to the river.

Specific objectives include:

- Annual projections of returns to the Connecticut River;
- A deterministic and stochastic option for model runs
- Life history inputs of Connecticut River shad
- Understanding the effect of upstream and downstream passage delay at projects
- Calibration of the model with existing data
- Analysis of the sensitivity of model inputs
- Analysis of sensitivity to different levels of up- and downstream passage efficiencies at all projects
- Multiple output formats including a spreadsheet with yearly outputs for each input and output parameter

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

3. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
4. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Service's goals are:

1. Minimize current and potential negative project operation effects on American shad spawning and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream from Holyoke Dam. A number of

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad populations, and numbers of shad passing Holyoke, Turners Falls and Vernon Dam have not met CRASC management goals.

Population and passage numbers past Holyoke have declined substantially from those totals in recent years, with average Holyoke passage numbers since 2000 of 229,876. Whole river population estimates have shown that approximately half of the returning population of shad pass upstream of Holyoke. Recent returns to Holyoke are far below management goals. Average passage efficiency of shad at Turners Falls (Gatehouse counts) and Vernon since 2000 has been 3.1 and 20.4 % respectively. These too are well below the CRASC management goals.

Safe, timely and effective up- and downstream passage along with successful spawning and juvenile production are necessary to help achieve shad management goals for the Connecticut River.

Nexus to Project Operations and Effects

Existing project operations and fish ladder efficiencies have a direct effect on shad populations in the Connecticut River. Poor upstream passage efficiencies and delays restrict river access to returning shad. Fish unable to reach upriver spawning grounds may not spawn or have reduced fitness or survival of young. Poor downstream passage survival and downstream passage delays affect outmigration and consequently repeat spawning, an important ecological aspect of the iteroparous Connecticut River shad population (Limberg et al. 2003).

The Service is concerned that poor passage efficiencies and delays at projects may be limiting access to upstream reaches of the river, altering spawning behavior, decreasing outmigration survival and contributing to the failure of the Connecticut River shad population to meet management targets (Castro-Santos and Letcher 2010).

Development of a population model will allow an assessment of individual project impacts on the population as well as the cumulative impacts of multiple projects. The model will allow managers to direct their efforts in the most efficient manner toward remedying the conditions that most impact the shad population.

Methodology

Population models are commonly used to assess anthropomorphic and natural impacts and are consistent with accepted practice. A model similar to this request was constructed for the Susquehanna River by Exelon (FERC #405, RSP 3.4). The model is constructed in Microsoft Access

Specific parameters that would be included in the model:

- Upstream passage efficiency at Holyoke, Turners Falls (Cabot, Gatehouse and Spillway Ladders), Vernon fishways, and any impacts associated with Northfield Mountain.
- Distribution of shad approaching the Turners Falls project between the Cabot Ladder and the spillway at the dam
- Downstream passage efficiencies at Vernon, Northfield Mountain, Turners Falls, and Holyoke projects for juveniles and adults
- Entrainment at Mount Tom and Vermont Yankee
- Sex ratio of returning adults

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

- The proportion of virgin female adults returning at 4, 5, 6, and 7 years
- The proportion of repeat spawning females at 5, 6 and 7 years
- Spawning success of females in each reach
- Fecundity
- Percent egg deposition
- Fertilization success
- Larval and juvenile in-river survival
- Calibration factor to account for unknown parameters such as at sea survival
- Options for fry stocking and trucking as enhancement measures
- Start year and model run years
- Start population
- Rates of movement to and between barriers
- Temperature, river discharge, and other variable of influence to migration and other life history events

The model should be adaptable to allow the input of new data and other inputs.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Neither First Light nor TransCanada have proposed any study to meet this need. Estimated cost for the study is expected to be low to moderate. As the model describes the impacts of multiple projects and two owners, both project owners would share the cost of model development.

Study Request 11: Upstream American Eel Passage Assessment at Turners Falls Dam (Docket Number p-1889)

Goals and Objectives

This study has two objectives:

1. Conduct systematic surveys of eel presence/abundance at Cabot Station discharge, Station #1 discharge, canal discharges, and Turners Falls Dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective locations to place upstream eel passage facilities.
2. Collect eels with temporary trap/pass devices from areas identified from surveys as potential locations of eel concentration to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

1. Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
2. Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed A Management Plan for American Eel (*Anguilla rostrata*) in the Connecticut River Basin in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...”

Management objectives in the plan include the following:

1. Protect and enhance eel populations where they currently exist;
2. Where practical, restore populations to waters where they had historical abundance;
3. Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
4. Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to upstream passage of American eel, the Service’s goals are:

1. Minimize current and potential negative project operation effects that could hinder management goals and objectives.
2. Minimize project-related sources of upstream passage delay, injury, and stress in order to facilitate access to historical rearing habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

The PAD contains no information relative to areas where eels seeking to move upstream concentrate downstream of the dam, or annual numbers of eels attempting to ascend past Turners Falls Dam. While eels have been known to ascend the Cabot Station ladder (A. Haro, U.S. Geological Survey, pers. comm.), its efficiency is unknown, and it is only operated during the American shad passage season (from April 1 through July 15). Eels are currently able to pass the Turners Falls Dam complex (as evidenced by documented presence of eels upstream), but the total number of eels attempting to pass Turners Falls and the proportion successfully passing the project is unknown (but suspected to be low). The downstream Holyoke Project has operated upstream eel passage facilities since 2004. Last year these

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

facilities passed over 40,000 juvenile eels. While there is rearing habitat in between the Holyoke and Turners Falls dams, some eels will attempt to continue upstream, and passage needs to be provided so these fish can access historical habitat.

These information gaps need to be filled so resource agencies can determine the best locations to site upstream eel passage facilities and assess whether operating the existing anadromous ladders would be an effective mechanism to move juvenile eels upstream past the project.

We also note that within the past seven years, the Service has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability (CESAR). On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made before any new licenses are issued for the projects.

Nexus to Project Operations and Effects

The project generates hydropower on the head created by the Turners Falls dam. This dam creates a barrier to upstream migrating eels. While some eels are able to pass dams, some are not, and the passability of a given dam depends on factors such as its height, hydraulics, presence of climbable surfaces, presence of predators, risk of exposure to heat or drying while climbing a dam, etc. The Turners Falls dam is high (35 feet above bedrock), and the majority of the dam face is dry during most of the upstream eel passage season. Design of the dam is not currently amenable to passage of eels by climbing. While flow is released to the bypass reach via a bascule gate (typically the one closest to the gatehouse), this would not facilitate eel passage, as bascule gates open outward and downward (i.e., requiring the eels to essentially swim nearly upside down to get over the gate). As mentioned earlier, the existing anadromous passage facilities are not designed to pass eels, and even if some eels are able to ascend the ladders, they may incur delays (in attraction or passage rates), be size-selective (e.g. velocity barrier for small eels presented by ~8 ft/sec flow through weirs and orifices), present a potential predation risk (predators in or near the fishways), and are not operated throughout the upstream eel passage season.

Methodology Consistent with Accepted Practice

1. Objective 1: Systematic Surveys

Surveys of eel presence and relative abundance should be conducted at regular intervals throughout the eel upstream migratory season (~1 May to ~15 October, or when river temperatures exceed 10 C). Surveys should consist of visual inspection and trapping in likely areas where eels may concentrate as they attempt to climb structures wetted by significant spill or leakage flow in the Turners Falls dam complex area. These locations include: Cabot Station downstream bypass outfall, Cabot Station spillway (including attraction water stilling basin), Cabot Fishway (dewatered state), USGS Conte Lab flume outfall, Number One Station outfall, various small turbine and process water outfalls from the Cabot Canal, Spillway Fishway attraction water stilling basin, and leakage points along the downstream face of Turners Falls Dam (bascule and taintor gates). Methods should include visual surveys (on foot, from a boat, or snorkeling) and trapping using small mesh (< 1/8" clear opening) baited eel

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

pots. Visual surveys should be performed once per week, at night, preferentially during precipitation events. Trap sets should be performed once per week, with an overnight soak time. Recorded data should include location, observation of eels (presence, absence, relative numbers, relative sizes, behaviors, time/date of observation), and survey method.

2. Objective 2: Trap/Pass Collections

Areas identified from Systematic Surveys as having significant number of eels present should be targeted as potential areas for permanent eel trap/passes, and should be initially assessed using temporary/portable trap passes. At a minimum (regardless of survey results), temporary trap passes should be installed at the following locations: Cabot Fishway attraction flow stilling basin (during dewatered fishway period), Number One Station outfall, and Spillway Fishway attraction flow stilling basin (during watered and dewatered fishway period), as these locations may be supplemented with additional attraction flow and have high potential for being concentration points for upstream migrant eels. Temporary trap/passes should be purpose-designed and built for each location, and operated throughout the eel upstream migratory season (~1 May to 15 October, or when river temperatures exceed 10 C). Ramp-type traps with supplementary attraction flow are preferred temporary trap/pass designs. Traps should operate daily, with catches quantified every 2-3 days. Recorded data should include location, trapping interval, absolute numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.

All collected eels from surveys should be released at their point of capture; those eels collected from trap/pass collections should be transported to and released above the dam in the Turners Falls Pool.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the survey component of the study would be low; a minimal number of personnel may be able to conduct the weekly surveys. The trap/pass component would require low to moderate cost (estimated at \$40,000) and effort.

In the PAD, the applicant has identified the need to assess issues related to upstream passage for American eels at the project, but indicates that it intends to rely on information from previously conducted studies and ongoing studies. The Service is not aware of any previously conducted or ongoing studies related to upstream eel passage.

Study Request 12: Impacts of Turners Falls Canal Drawdown on Fish Migration and Aquatic Organism Populations (Docket Number p-1889)

Conduct a study to quantify impacts of the annual Turners Falls Canal drawdown on emigrating and resident fishes, freshwater mussels and mudpuppies in the canal.

Goals and Objectives

Quantitatively assess the effects of the Turners Falls Canal drawdown on diadromous fishes and other aquatic organisms known to be present in the canal during the annual drawdown. Objectives of this study request include:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. Determine whether juvenile shad and American eel abundance in the canal increases leading up to the time of its closure, due to delays in downstream passage (e.g., is fish accumulation occurring?)
2. Determine level of mortality for juvenile sea lamprey from exposure of burrow habitats;
3. Conduct surveys to determine aquatic organisms (fishes, freshwater mussels, and mudpuppies) present in the canal during the drawdown, their densities, status (stranded, dead, alive), and locations (mapping to document habitat, substrate type, wetted , at complete drawdown);
4. Evaluate measures to minimize aquatic organism population impacts of the canal drawdown.

Other submitted Study Requests compliment or directly relate to this project activity and assessing project effects, including the resultant effects of all river flow being passed over the Turners Falls Dam as spill (e.g., downstream juvenile shad study request and American eel movement and survival request).

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, has the stated goal of “*Protect, enhance, and restore Atlantic coast migratory stocks and critical habitat of American shad in order to achieve levels of spawning stock biomass that are sustainable, can produce a harvestable surplus, and are robust enough to withstand unforeseen threats,*” and includes the following objective:

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

And recommendation:

2. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to diadromous fishes, the Service’s goals are:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. Minimize current and potential negative project operation effects on diadromous fishes, including juvenile shad, adult silver eels, and sea lamprey ammocetes.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), Silvio O. Conte National Fish and Wildlife Refuge Act (P.L. 102-212; H.R. 794), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Existing information in the PAD does not provide data on the population size or survival rates of juvenile American shad, American eels, or juvenile sea lamprey located in the power canal during the de-watering process. The power canal is dewatered in early September of each year for over a one week period to perform facility maintenance, inspections, and repairs including substantial silt removal and bank repairs. Historically, the canal drawdown occurred in July, but approximately five years ago it was moved to September, where it has occurred annually since then, with the exception of 2010. The agencies were informed in a letter by FLP that the shift to September was at the request of the Independent System Operator –New England (ISO-NE) to avoid peak load months of June through August. Studies conducted by the previous operator, Northeast Utilities Service Company (NUSCO), to assess downstream clupeid survival and use (1991 and 1994 studies at Cabot Station) support the contention that juvenile shad out-migration is occurring within the current drawdown time frame. There are no data to suggest that out-migration would occur earlier than 1 August, but likely does begin in the month of August (O'Donnell and Letcher 2008). Based on these data, CRASC altered its Fish Passage Notification Letter for Downstream Passage Operations for juvenile shad and herring to require the Cabot Station downstream bypass to begin operating on 15 August in 2010 and then moved the date to 1 August in 2011

It is unknown, whether the power canal may, through potential mechanism(s) of delay due to its configuration or operation, cause out-migrating juvenile shad to accumulate in the canal. This information gap leads to concerns that migrant numbers may be elevated beyond simple extrapolations of surface area comparison in the canal to main stem habitat. In the PAD, FLP indicates that the Cabot Station forebay in the vicinity of the intake has a maximum depth of 60 feet, while the existing near-surface downstream bypass structure at the Cabot Station is designed to operate only within a depth of six feet of the surface. As a result, the downstream bypass only operates effectively for a short period during the drawdown period (timing of this is unknown). The only points of egress, once the bypass becomes unavailable, are through the turbines at Cabot as well as at Station 1, and eventually at the Keith Street gate located well upstream from the Cabot Station intakes. It is unknown what the survival rates are for these passage routes, what proportion of fish are using each route, what number may become stranded and their survival rates, and how many fish are subjected to this situation. The related Study Requests on downstream juvenile shad outmigration and American eel outmigration outline objectives that would address some of these information gaps.

There is also a paucity of information relative to the disposition of fish moving downstream in the impoundment during the canal drawdown. Once the Turners Falls Gatehouse closes its gates, all inflow passes over the dam; a situation unique to this brief one week annual time

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM
period. Survival rates for outmigrating juvenile American shad and adult American eel moving past the project during the period of spill are not known.

Lastly, there exists an information gap regarding the fate of juvenile sea-lamprey (known as ammocetes) that reside in the soft substrate materials located in much of the lower or downstream end of the canal (personal communication, Boyd Kynard). In previous drawdowns, thousands to tens of thousands of desiccated ammocetes have been observed (Matt O'Donnell, personal communication, USGS Conte Lab). However, the distribution and abundance of ammocetes in the canal as well as mortality rates for ammocetes during the drawdown period has not been quantitatively determined.

Nexus to Project Operations and Effects

Previous studies at Cabot Station have documented that juvenile American shad and American eel migrate through the project area during the canal drawdown period. During normal operations (where canal water level elevations are stable), downstream migrants are able to utilize the Cabot bypass facility; however, as the canal water level is drawn down, the bypass is no longer available, and the only routes of egress are through the turbines at Cabot Station and Station 1, unless the Cabot Station spill gates are utilized (the spill gates have a canal depth limitation of approximately 16 feet). Turbine entrainment at hydropower projects has been shown to cause injury and mortality to fishes.

The annual canal drawdown was formerly conducted in July. In response to ISO-NE's request that FL conduct the drawdown outside of the June through August period, FL moved the drawdown to a period of time when diadromous fishes are known to be moving through the project area.

Once the canal has been drawn down, isolated shallow pools are left standing until the canal is refilled. During this period, fish (including lamprey ammocetes), amphibians, and benthic invertebrates are prone to desiccation, predation or other sources of mortality or impact.

Methodology Consistent with Accepted Practice

The methods presented here are consistent with the study requests addressing downstream juvenile American shad passage and downstream American eel passage, with an emphasis on addressing survival and movement immediately prior to and during the canal draw down. Hydroacoustic monitoring immediately upstream of the Turners Falls Gatehouse, as well as upstream of opened dam gates for spill, will provide data on the timing, frequency and magnitude of natural wild juvenile shad movement into these areas, particularly the power canal. The abundance of juvenile shad moving into the canal can be derived and compared with similar data obtained with hydroacoustic equipment monitoring upstream of the Cabot Station intake and bypass, for comparisons. Juvenile shad will be PIT tagged, released, and monitored in the canal, for movements, timing and location including Station 1 canal and forebay. PIT tagged fish will be detected at the Cabot Bypass Sluice sampler. Juvenile fish should be specifically targeted for release immediately prior to drawdown to assess survival and movement in and through the canal. Surveys of sea lamprey ammocetes should be conducted by a stratified sampling design based upon substrate.

Lamprey density surveys, immediately after drawdown and in a subsequent later survey, may derive rates of change in observed densities and their status (live, moribund, dead); appropriate methods would need to be discussed. Surveys of remaining ponded water should be conducted immediately following drawdown and at later intervals (mid- week and end of

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

week) to compare species occurrence and densities (relative abundance) which will be used to develop catch-curve analyses that can inform rates of mortality to the observed populations.

Assessments of freshwater mussels should also be conducted to quantify drawdown impacts. As with lamprey, the assessment can be based on sampling identified habitats in a stratified, random design, over the three time periods noted (initial drawdown, mid week, and end of week), tracking changes in densities and status of observed individuals among areas. Sub-sampling, with sufficient repeated measures to determine variability and acceptable level of precision of data will inform the required sampling intensity that will be needed. This sampling intensity will be determined as the study occurs and may vary among identified species. Comparisons among the three time periods for measures of density and status will inform the evaluation of project effects for juvenile shad, sea lamprey ammocetes, freshwater mussels and mudpuppies

The canal drawdown mitigation assessment involves evaluating alternative drawdown protocols to minimize impacts to resident and migratory fish, mussels and amphibians inhabiting the canal. Alternatives should include: (1) moving the drawdown to a time of year outside of migration seasons; (2) keeping or moving the timing of the drawdown, but utilize technologies to keep the majority of the canal wetted during the drawdown (e.g., portadams in the forebay immediately upstream of the trashracks and at other canal intakes in need of maintenance); and (3) in combination with alternative #2, assess whether other existing infrastructure within the forebay could be used to pass fish safely out of the canal (e.g., low level outlets, deep gates, side spillway boards, etc.). The assessment should compare the merits and drawbacks of each alternative and provide an order of magnitude cost estimate for implementation.

Level of Effort/Cost, and Why Alternative Studies will not suffice

This Study Request has many elements that overlap directly with a larger scale downstream juvenile American shad passage and downstream American eel passage study requests. With equipment costs principally covered in those requests, many components of what has already been proposed will be used in this study. However this request does include some specific elements not specified in the other two larger requests. The study cost and effort are expected to be low to moderate. Some additional radio tags and balloon tags with additive days of field work to accurately assess impacts specific to the drawdown period will be required. Surveys for identified aquatic organisms will take several days during the drawdown period as well.

The canal drawdown mitigation assessment should require a low to moderate level of effort and cost. One staff person would evaluate alternative drawdown protocols. This should take less than one week to complete.

The applicant did not propose any studies to meet this need in the PAD.

Study Request 13: Three-dimensional Computational Fluid Dynamics (CFD) Modeling in the Vicinity of Fishway Entrances and Powerhouse Forebays (Docket Number p-1889)

Goals and Objectives

The goal of this study is to determine the flow field conditions that exist in and around the fishway entrances, and upstream of both Turners Falls powerhouses (Station 1 and Cabot). The information from this request is meant to be coupled with data from the telemetry study such that a comprehensive understanding of fish behavior is developed.

The objective of this study is to develop a series of maps that show color contour maps of velocity magnitude at discharges that have been agreed upon by the resource agencies and the licensee. With respect to upstream passage, the results will show approach velocities and orientation within the approach zone of the fish that may create a response in fish. This information can be coupled with telemetry data (from the requested shad telemetry study) and passage counts to understand which conditions are optimal for guiding migrating fish to the fishway entrances and for stimulating fishway entry. With respect to downstream migration, the results will show velocities and orientations in front of each powerhouse. At Cabot Station, the results will indicate to what degree, if any, flow directs downstream migrating fish towards the surface bypass weir. At Station 1, we will have an improved understanding of the magnitude of velocity in front of the turbine intakes.

Resource Management Goals

The management goals of this study request are to obtain information that will help assist in designing effective upstream fishways for upstream migrating trust species and to reduce impingement, entrainment and delay for downstream migrating fish. CFD models are a relatively cost effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating and which spillway gates are releasing water can all be examined. As stated, the results from this study are meant to be used along with the data generated from the telemetry study. The combined analysis from these two data sources can help assess which flow conditions are most advantageous for migrating trust species to enter the fishway under current and proposed conditions.

As for downstream migration of adult and juvenile shad, and adult eel, the results from the models will reveal flow magnitude and direction in front of each powerhouse. Given the limited information that currently exist on survival through Cabot and Station 1, our management goal is to direct as many downstream migrating fish as possible towards the uniform acceleration weir and downstream bypass. With respect to upstream passage, we want to maximize the number of fish that find and enter the fishway entrances.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor, NMFS, is a federal resource agency.

Existing Information and the Need for Additional Information

To date, no CFD modeled data exist in front of either fish ladder, nor do they exist in front of either powerhouse. Some preliminary modeling has been done downstream of the Gatehouse, but changes to the gatehouse entrances would require updated modeling. It is our understanding that the licensee has worked with the firm Alden to develop a CFD model of

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

the upper power canal and that elevation survey data from the power canal also are available. Detailed 2-dimensional movement data on shad are available from observations made between 2003 to 2005 and 2010 to 2012. By coupling and analyzing these two data sets, flow and fish movement, we believe this will have substantial benefits to our management efforts.

When designing upstream passage structures, a site assessment is critical. The development of these models gives resource agencies valuable information into the hydraulic cues which may elicit a response from upstream migrants. For downstream passage, the U.S. Fish and Wildlife Service has approach velocity guidelines; the output from these models would inform the resource agencies under what conditions appropriate approach velocities are being met and when they are being exceeded.

Project Nexus

The Turners Fall Project has direct impacts to upstream and downstream migrating shad and eel. With respect to upstream migration, the auxiliary water system (AWS) plays a critical role in determining whether or not fish are attracted to the entrance. The results from this study would allow us to assess how well the AWS is performing and under what conditions it attracts the most fish.

With respect to downstream migration, as a general rule, fish tend to follow the flow. If flow fields are directing fish towards the turbine intakes, the results from this study will indicate that. The development of a CFD model under existing conditions also informs the design of future modifications. The development of a CFD model could be used to improve the survivability of downstream migrating shad and eel.

Proposed methodology

A 3-dimensional CFD model has become an increasing common standard of analysis at hydro-electric projects around the nation. Within the Northeast region, we have seen these types of models developed at the Holyoke (P-2004), Brunswick (P-2284), Shawmut (P-2322), Milford (P-2534) and Orono (P-2710). We would expect to engage with the licensee in terms of determining the appropriate area and flows to be modeled. We expect that the spatial extent of the model at each study site will vary. Given the large number of ways that output from these models can be presented and the near infinite number of flows that could potentially be modeled, we would expect to consult with the licensee to reach agreed upon modeling efforts and scenarios to be examined.

Level of Effort and Cost

The cost of developing, running and testing a CFD model can vary tremendously; one large variable is determining the cost is based on the amount of existing bathymetric data the applicant currently has access to. We roughly estimate the cost of each CFD model could run as high as \$50,000 assuming no bathymetric data currently exists. Proactive communication with resource agencies will reduce the cost and iterative effort. Given the above mentioned projects where this level of effort has occurred for other projects that have proposed to amend their license for various reasons, we see the level of effort as commensurate with the other projects given that the applicant is requesting a renewal of its existing license.

Study Request 14: Evaluate the frequency and impact of: 1) emergency water control gate discharge events and: 2) bypass flume spill events, on

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

shortnose sturgeon spawning and rearing habitat in the tailrace and downstream from Cabot Station (Docket Number p-1889)

This evaluation should directly address the impact of sediment disturbance and excessive velocities on habitat in Cabot Station tailrace and downstream resulting from emergency water control gate discharge events and bypass spill events and effects of spill from the downstream fish bypass sluice on shortnose sturgeon spawning and incubation.

Goals and Objectives

The goal of this study is to determine appropriate scenarios for operation of the emergency water control gates and bypass flume that will be sufficiently protective of shortnose spawning and rearing below Cabot Station from excessive water velocities and exposure to abrasive sediments dislodged and transported across spawning and rearing areas.

Furthermore, avoidance or minimization of rapid fluctuations in flow is also a goal of this study applicable to the operations of the emergency water control gates and bypass flume.

The objective of the study will be to determine how often the emergency water control gates are operated to discharge large quantities of water and evaluate the impact of these events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot Station. Another objective is to understand the operation of the bypass flume that result in bypass flume spill events and evaluate the impacts of these spill events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot station. Even when bottom velocities fall within the range optimum for shortnose sturgeon spawning, rapid fluctuations may result in sediment transport having a harmful impact on developing eggs and embryos.

Specific Objectives include:

- a. Emergency water control gate discharge events
 - i. Field verification during operation of the emergency water control gates during a range of spill and discharge conditions is necessary during years 2014 and 2015 if emergency water control gates will continue to be operated during shortnose sturgeon spawning and rearing (April 15th –June 22nd).
 1. Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the emergency water control gates that will avoid or minimize negative impacts to spawning and rearing habitat.
- b. Bypass flume spill events
 - i. Field verification during bypass flume spill events under a range of spill and discharge conditions is necessary during years 2014 and 2015 if bypass flume spill events continue to be a part of future project operations and will occur during shortnose sturgeon spawning and rearing (April 15th and June 22nd).
 1. Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the bypass flume that will avoid or minimize negative impacts to spawning and rearing habitat.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Resource Management Goals

NMFS seeks to understand current emergency water control gate bypass flume operations and associated impacts to determine potential operation scenarios that avoid or minimize negative effects on shortnose sturgeon spawning and rearing.

Public Interest

The requestor is a natural resource agency.

Existing Information

The emergency water control gates are used to spill large amounts of water and Cabot Station also spills water from the bypass flume (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007). These large spill events created a plume of turbid turbulent flow, which caused some females to leave the area (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007).

Additional spill events create a scour effect on the bottom and the scoured sediments are then pushed downstream over, or deposited on spawning and rearing shoals where an entire years class of ELS may be destroyed (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007).

Information included in the PAD does not address operation of the emergency water control gates or bypass flume and impacts on shortnose sturgeon spawning and rearing.

Nexus to Project Operations and Effects

The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project [insert citations]. One of the two critical shortnose sturgeon spawning and rearing areas in the Connecticut River is located within the Cabot Station tailrace and impacted by the project's discharges, including spill from the emergency water control gates and bypass flume. This section of the Connecticut River also contains habitat that supports important spawning and rearing areas for migratory fish such as American shad and American eel. Current operations of the emergency water control gates and bypass flume create flow dynamics that are not sufficiently protective of shortnose sturgeon spawning and rearing. Results of this study will be used by the Service to determine recommendations for operation of the emergency water control gates and bypass flume that will avoid or minimize sedimentation and improve bottom velocities that are sufficiently protective of shortnose sturgeon spawning and rearing.

Methodology Consistent with Accepted Practice

River hydrology modeling is commonly employed at hydroelectric projects to assess implications of project operations on the river environment. It is assumed that the planned hydrologic modeling can incorporate emergency water control gate operations and associated impacts. Thus, an additional model would not be required for this request.

Field assessment will be needed to collect sedimentation and bottom velocity data at the emergency water control gates and fish bypass sluice discharge areas to determine what operational scenarios of those structures avoid or minimize impacts to shortnose sturgeon spawning and rearing. Velocity gauges will be employed to collect data on bottom velocities associated with project operations at Cabot Station. Coordination of gauge placement for this request with the field measurements for the instream flow study should help minimize the number of necessary gauges. Field assessment of sedimentation may be collected using a variety of techniques. One potential method of collection of sedimentation data would be to set fine-mesh nets similar to shortnose sturgeon larval collection nets; these nets may show

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

changes in the amount of dislodged substrate material that travels along the spawning site as a result of powerful releases at both the Cabot spillway and bypass flume.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Field verification for this study request will likely be coordinated with other field work for related study requests. It is not expected that the required field work for this request will result in significant additional cost and effort beyond what is expected for field work related to the instream flow study request. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

Study Request 15: Determine the Fish Assemblage in the Turners Falls and Northfield Mountain Pumped Storage Project-Affected Areas (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

The goal of this request is to determine the occurrence, distribution, and relative abundance of fish species present in the Project affected areas of the Turners Falls and Northfield Mountain Project Areas, which potentially includes Species of Greatest Conservation Need (SGCN) for Massachusetts, New Hampshire, and Vermont.

Specific objectives include:

- 1) Document fish species occurrence, distribution and abundance within the project affected area along spatial and temporal gradients.
- 2) Compare historical records of fish species occurrence in the project affected area to results of this study.

Resource Management Goals

The Massachusetts Division of Fisheries and Wildlife, New Hampshire Fish and Game Department and the Vermont Fish and Wildlife Department each have as a mission the protection and conservation of fish and their habitats. Riverine fish species are an important component of the river's ecology and are the basis for the sport fishery. Furthermore, several of the states' SGCN have been documented in the project-affected area.

Determining species occurrence, distribution, and abundance will better clarify what species occur in the project area both spatially and temporally, relative to habitats which may be affected by project operations of the Turners Falls or Northfield Mountain Pump Storage projects. This information will better inform other results from other study requests that will be examining project operation effects on various aquatic habitats, water quality and other related concerns such as entrainment concerns at NFMPS. This information will be used to make recommendations and provide full consideration for all species, including those that might not otherwise be known to occur in the project-affected area and impacts that may affect their population status through direct or indirect effects of the projects.

Public Interest

The requestor is a natural resource agency.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Existing Information

A thorough and comprehensive assessment of the fish assemblage present in the project-affected areas of the Turners Falls and NFMPS projects is lacking. The PAD for these projects sites notes resident fish surveys conducted by the State of Massachusetts in the early to mid 1970s and a limited 2008 sampling effort by Midwest Biodiversity Inst. (contracted by EPA). The PAD identifies a total of 22 fish species in the project area which omits, as an example of its limited information basis, northern pike, tessellated darter, burbot, eastern silvery minnow, and channel catfish (Ken Sprankle, USFWS, and Jessie Leddick, MADFW, personal communication). It is unknown how many other species may inhabit or utilize aquatic habitats in the projects area, potentially including species of greatest conservation need.

The most relevant recent fish survey study related to the project affected areas is a Connecticut River electrofishing survey conducted in 2008 (Yoder et al., 2009). While some sampling was conducted in both project areas during the 2008 survey, this survey did not have the same goals and objectives as those outlined above. Due to the design of the study limitations in geographic/habitat type coverage both spatially and temporally, and the use of a single gear type, limits the use of these data and that synthesized data may not be a full representation of species occurrence in the project affected areas. It follows that since information is limited regarding the composition of the fish community and their use of habitats in the project-affected area, project impacts on fish species are also unknown.

Nexus to Project Operations and Effects

Project operations have the potential to directly impact fish species life history requirements, biological interactions, and habitat quantity and quality. For example, headpond and tailwater water level fluctuations could dewater important spawning areas, or affect habitat availability, thus limiting productivity of fish species by direct impacts to their spawning success or indirectly by limiting the spawning success of forage fish species. Accordingly, a thorough understanding of the current fish assemblage structure and associated metrics are needed in order to examine any potential project-related impacts. A Study Request to examine project effects on aquatic habitats, as well as impacts to spawning habitats (e.g., sea lamprey and black bass) has been submitted and will compliment this request.

Methodology Consistent with Accepted Practice

An accepted and robust field sampling design (e.g., as described in Pollock et al. 2002 or MacKenzie et al. 2006) and accepted methods for collecting fish species likely to be present in the project-affected areas (Bonar et al. 2009) should be used to conduct field surveys. Randomly sampling multiple habitat types using a multi-gear approach will be required to ensure that all fish species present are sampled. The spatial scope of the study will be from the headwaters of the Turners Falls pool downstream to Sunderland, Massachusetts, and will omit the upper reservoir of Northfield Mountain Pump Storage Project. Sampling should occur at each selected site across multiple seasons (spring, summer, and fall). Digital photographs should be taken to avoid misidentification of certain species such as Cyprinids.

The sampling design should include replicate samples for estimation of species detection probability. Sample replicates may be gathered temporally, using different methods, by independent observers, or by randomly sampled spatial replicates (MacKenzie et al. 2006). For each replicate sample, data that may be important for describing variation in species occurrence and presence/absence should be collected and recorded, such as gear type, mesohabitat type, depth, velocity, flow, water temperature, substrate, time of day, day of year, presence of cover, proportion of vegetation cover, size of individuals collected (juveniles may select different habitat), and/or other factors as determined by a qualified biologist. Species

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

detection, occurrence, and/or abundance and related habitat measures on these parameters should be estimated using methods as described by Kery et al. (2005), MacKenzie et al. (2006), Wenger and Freeman (2008), or Zipkin et al. (2010).

This will be a one year study provided river discharge conditions fall within 25th to 75th percentile for weekly averages. Based upon this study's results, and the additional information obtained on requests to survey aquatic habitats and littoral zone fish spawning, an additional study may be required if evidence of project operation affects on population status or habitat for identified species.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The cost of the study will be moderate to high as seasonal sampling with several types of gear will be required. However, cost will also be partially dependent on the number of sites sampled, the number of sample replicates, and the extent of the covariate data that are measured, all which may be flexible. Based on first year study results, a second year of sampling or specific studies examining impacts of project operations on specific fish species may be needed and requested. Provided the collected data are of high quality, analysis and synthesis should take approximately 10-20 days. FirstLight did not propose any studies specifically addressing this issue.

Study Request 16: Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations (Docket Number p-1889) (Docket Number p-2485)

Develop a river flow model(s) that are designed to evaluate the hydrologic changes to the river caused by the physical presence and operation of the Turners Falls Hydroelectric Project and the interrelationships between the operation of all five hydroelectric projects up for relicensing (i.e., P-1889 Turners Falls Hydroelectric Project, P-2485 Northfield Mountain Pumped Storage, P-1904 Vernon Hydroelectric Project, P-1855 Bellows Hydroelectric Project, P-1892 Wilder Hydroelectric Project) and river inflows. The flow studies should assess the following topics:

1. Conduct quantitative hydrologic modeling of the hydrologic influences and interactions that exist between the water surface elevations of the Turners Falls Project impoundment and discharges from the Turners Falls Dam and generating facilities and the upstream and downstream hydroelectric projects. Data inputs to and outputs from the model(s) should include:
 - a. Withdrawals from the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project, FERC No. 2485,
 - b. Discharges to the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project,
 - c. Discharges into the Turners Falls impoundment from the Vernon Project, FERC No. 1904 and other sources.
 - d. Existing and potential discharges from the Turners Falls Project generating facilities and spill flows.
 - e. Existing and potential water level fluctuation restrictions (maximum and minimum pond levels) of the Turners Falls impoundment and downstream flows from the project
 - f. Existing and potential required minimum flows and/or other operation requirements at each of the four upstream projects.
 - g. Minimum discharge flows ranging between 2,500 and 6,300 cfs in the bypass reach from April 15th through June 22nd to support spawning, rearing, and outmigration of shortnose sturgeon at Rock Dam.
2. Document how the existing and potential outflow characteristics from the four upstream projects affect the operation of the Turners Falls Project including downstream flow releases and Turners Falls impoundment levels.
3. Assess how the operation of the existing Turners Falls Project and upstream projects affect Holyoke Project (P-2004) operations including:
 - a. How Turners Falls Project flow fluctuations affect Holyoke impoundment water levels, with emphasis on the influence on the water levels on listed Puritan tiger beetle habitat at Rainbow Beach in Northampton, MA. and assess what changes would be needed in Turners Falls operations to stabilize water levels at Rainbow Beach.
 - b. How Turners Falls Project operations affect Holyoke Project discharges and what changes in Turners Falls operations would be needed to reduce fluctuations in the discharges from the Holyoke Project.
4. To the extent predictable and practical, incorporate the potential effects of climate change on project operations over the course of the license.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Goals and Objectives

Determine the extent of alteration of river hydrology caused by operation of the project and the interactions between upstream project operations, Turners Falls operations and downstream operations at the Holyoke Project. The models will provide necessary information on what changes can be made to each of the five project's flow releases and/or water levels restrictions, and how those changes affect downstream resources.

Specifically, for the Turners Falls Project continuous minimum discharge flows in the Turners Falls bypass reach need to be no less than 2,500 cfs during shortnose sturgeon spawning, rearing, and outmigration (April 15th – June 22nd). Incorporating these parameters into the model will inform what changes, if any, need to be made to operations of upstream projects to accommodate such flows.

As other specific modifications of the operations of each of the projects are identified based on results of other requested studies, these desired conditions will need to be input into the models to assess how each change affects that project and other project operations and the implications of those changes on other resources and/or the ability to achieve desired operational changes at other projects.

Resource Management Goals

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
3. Assist FERC to ensure that the continued operation of the facility is not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources, the Service's goals are:

1. Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
2. Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
3. Minimize current and potential negative project operation effects on water quality and aquatic habitat.
4. Ensure that project operations are not likely to jeopardize the continued existence of shortnose sturgeon.
5. Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing within the Montague spawning area (i.e. Rock Dam and Cabot Station spawning sites and associated early life stage rearing areas).

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor is a resource agency.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Existing Information

Available information in the PAD does not indicate how project operations have altered downstream hydrology, which may affect resident and migratory fish, macroinvertebrates, rare, threatened, and endangered species, aquatic plants and other biota and natural processes in the Connecticut River from below the Vernon Dam downstream to the Holyoke Dam.

Information in the PAD also does not reflect data analyzed in Kynard et al. 2012, which identifies minimum discharge thresholds for shortnose sturgeon spawning and rearing at the Rock Dam spawning site. Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period (April 27–May 22nd) (Kynard et al. 2012, chapter 3). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 ELS captured, spawning period was 17 days) even though no spawning was detected at Rock Dam (Kynard et al. 2012, chapter 3). Discharges in 1995 at Rock Dam had dropped below 2,500 cfs by March 26th (Kynard et al. 2012, chapter 3), showing that even though 1995 saw the largest number of pre-spawning adults, none spawned at Rock Dam. This may indicate the need to have adequate flow well in advanced of spawning. Discharge reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning cite and not return even if flow increased to acceptable levels later during the spawning period. Researchers observed that substrate did not change during fluctuating flows and thus cessation of spawning is likely due to velocities falling below the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kynard et al. 2012, chapter 3). These data represent the best available scientific information and indicates that the current minimum flow thresholds at the project are not adequate for the protection of endangered shortnose sturgeon. All modeling efforts described above must incorporate the identified minimum flow and temporal parameters.

Nexus to Project Operations and Effects

The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (400 cfs from 5/1 through 7/15, then 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flow below the projects of 1,433 cfs. The project operates as a daily peaking project, often with large, rapid, daily flow fluctuations between the minimum and project capacity (15,928 cfs) and fluctuations in headpond elevation (175' to 186' MSL). These changes affect biotic habitat and biota upstream and downstream of the project. Project operations and potential changes to operations to mitigate impacts are influenced by inflows and operations of upstream peaking projects and the Northfield Mountain Pumped Storage Project operations and potential changes in operations of each project could affect the ability to achieve desired operational changes at other projects. Results of river flow analyses will be used to develop flow-related license requirements and/or other mitigation measures.

Methodology Consistent with Accepted Practice

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess implications of project operations on the river environment.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Level of effort and cost of model development are expected to be moderate but to be valuable in developing license conditions, the model(s) will need to be run under various scenarios throughout the relicensing process to assess the implications of changes to the operations of each project on other projects and other resources. Therefore, ongoing consultation and re-running of the model(s) are likely to be needed throughout the relicensing process. The

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

modeling exercise will also require coordination and cooperation between First Light and the upstream licensee to assure that the model inputs and outputs can be accurately related.

We would anticipate that the expected level of effort and anticipated costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., Conowingo, FERC No. 405).

Study Request 17: Impacts of Water Level Fluctuations on Riparian and Aquatic Vegetation Including Invasive Species and their Associated Habitats in the Turners Falls Dam Project Impoundment (Docket Number p-1889) (Docket Number p-2485)

Conduct a study to quantify impacts of reservoir fluctuation on riparian, wetland, Emergent Aquatic Vegetation (EAV), Submerged Aquatic Vegetation (SAV), littoral zone and shallow water aquatic habitats in the Turners Falls Dam impoundment.

Goals and Objectives

The goal of this study is to obtain baseline information on riparian, wetland, emergent and submerged aquatic vegetation, and associated shallow water aquatic habitats (subject to operational inundation and exposure to near exposure) known to occur in the project area. Information would be used to determine whether riparian, wetland, EAV and SAV, littoral, and shallow water (e.g., mid river bars and shoals) habitats are impacted by current water level fluctuations permitted under the Turners Falls and Northfield projects' licenses and whether these vegetation types and shallow water habitats can be protected and restored by modifications to project operations or other mitigation measures. This analysis needs to take into account existing and potential future limits on pond level fluctuations intended to limit recreation impacts, and the interactions of any changes in pond level fluctuation range or frequency and discharge changes under a new licenses of the Turners Falls and upstream projects. This information is needed to determine whether the projects operation affects plants, habitat, and wildlife in the project area, whether aquatic vegetation and its habitats can be enhanced by modifications to project operations or other mitigative measures, and whether there is any unique or important shoreline or aquatic habitats that should be protected.

The specific objectives of the field study, at a minimum, include:

- Quantitatively describe and map wetland types within 200 feet of the shoreline, and describe associated wildlife;
- Delineate, quantitatively describe, and map all wetland types including invasive species and wildlife observed (e.g., bald eagle nesting, water fowl nesting) within 200 feet of the shoreline, and the extent of this habitat if it extends beyond 200 feet; and
- Quantitatively describe (e.g., substrate composition, vegetation type and abundance) and map shallow water aquatic habitat types subject to project operation inundation and exposure, noting and describing additional areas where water depths at lowest operational range are wetted to a depth less than one foot (flats, near shore areas, gravel bars, with very slight bathymetric change);

A second year of study may be required should river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period.

The field study should produce a habitat inventory report that includes:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

- The results of the field study in the form of maps and descriptions;
- An assessment of project effects on wetland, riparian, littoral zone vegetation and shallow water habitats, invasive plant species, and wildlife habitat at the project; and
- Recommendations for any necessary plant, habitat type, or wildlife, protection and/or invasive species control measures.

Resource Management Goals

Protect and restore native riparian, wetland, EAV, SAV, littoral and shallow water habitat (i.e., spawning and or nursery areas for aquatic organisms) in the project reservoir.

Public Interest

The requestor is a resource agency.

Existing Information

Existing information in the PAD does not quantify EAV and SAV in this area, or other shallow aquatic habitat types and physical features (e.g., depths, substrates, wood structure) that are the environment for aquatic biota in the project area. The PAD does provide some limited monitoring data for 2012 (2 locations) on water surface elevations that show daily fluctuations, in the upper third of this impoundment, that varied over 4 feet on a daily cycling frequency, with fluctuations generally in the 2 foot range in low flow months for the data provided in the PAD. The current license does permit a greater pool elevation operational fluctuation, up to a 9 foot change in elevation, based on the Turners Falls Dam water elevation. In the PAD it is noted these operational fluctuations under most circumstances at the Turners Falls Dam are within 3.5 feet.

In the PAD it is noted that FLP would like to expand its NMPS upper reservoir capacity (by up to 24%), how this may affect project operations and the habitats noted in this request is unknown. It is also noted that water is typically pumped to the upper reservoir in evening and generation back to the river occurs once to twice daily, in daytime hours, based upon power needs and power value. Under current license conditions, provided set thresholds for minimum flow and Turners Dam current license elevations are met, the NMPS may operate with no restriction in timing, frequency, or magnitude for pumping or generation. No data were provided on the operation of the NMPS plant over time relative to data on pumping and generation on an hourly basis, averaged values were provided over monthly periods. It is unclear what the actual timing, frequency and magnitude of these NMPS operations are over the course of a year and how that relates to; aquatic plant species establishment, growth, survival, littoral zone or other shallow water habitat fish spawning periods and their effects on these fishes (reproduction success and subsequent recruitment, e.g., bass and fall fish nests) in available and utilized habitat, and how the quantity and quality of these shallow water habitats are effected by project operational manipulation/alteration, as currently permitted or proposed.

The PAD provides lists of plant and wildlife species whose native ranges overlap with the project area, but it does not provide any baseline information on known occurrences of these species in the wetlands, riparian, littoral and shallow water habitats, within or adjacent to, the project area. Plant and wildlife occurring in these habitats may benefit from protection, mitigation, and enhancement (PMEs) measures, given the potential effects of continuing the current semiautomatic peaking operating regime. In addition, a large scale sediment discharge from NMPS resulted in regulatory actions by FERC, the EPA and MADEP in 2010. Continuing and as yet unresolved management plan measures relative to sediment and NMPS project operations, are further concerns for shallow water, littoral zone, and wetland habitats.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

The Atlantic States Marine Fisheries Commission, Atlantic Coast Diadromous Fish Habitat: A Review of utilization, threats, recommendations for conservation, and research needs (ASMFC 2009), contains a review of habitat information for these species. Recommendations in this report include: Maintain water quality and suitable habitat for all life stages of diadromous species in all rivers with populations of diadromous species.

Nexus to Project Operations and Effects

Water level fluctuations due to project operations could affect EAV and SAV habitat as well as the quantity and quality littoral and shallow water habitat. These operational water level fluctuation effects are expected to impact fish species use of these habitats and may affect spawning fishes reproductive success and subsequent population recruitment including but not limited to American shad, blueback herring, sea lamprey, fall fish, and bluegill, which spawn in mid to late spring through early summer in areas subject to daily or more frequent water level fluctuations.

The current operating mode, as well as the unknowns with proposed upper reservoir expansion, may affect wetland riparian, littoral and other shallow water habitats and promote the introduction and expansion of invasive plant species through fluctuating water levels. A study that explains the relationship between the proposed mode of operation and the type and quantity of wetland, riparian, littoral, shallow water habitats, and invasive species affected would help inform a decision on the need for protection and/or control of these resources in the license.

Methodology Consistent with Accepted Practice

The PAD currently contains maps portraying general wetland types from the Cabot Station tailrace upstream to the Vernon Dam. In addition, the Service understands that the detailed bathymetry exists for the Turners Falls impoundment. The proposed study should utilize this existing information in conjunction with field surveys designed to describe the characteristics of each mapped wetland, riparian, littoral and shallow water habitat including plant species composition, relative abundance/density, habitat quality, and land use. These surveys should be conducted to describe these habitats at the lowest water level operational range permitted on a daily operation schedule, under low flow conditions. Information collected should include:

- Plant species composition, and their relative abundance/density and condition/structure (e.g., seedlings);
- Structured data, including estimates of average heights and aerial cover of each vegetation layer (specifically denoting invasive species);
- Aquatic habitat substrate composition, quantity (i.e., percent types and area), wood structure (relative abundance measure applied by area), water depths (inundated, exposed, and water less than one foot);
- Predominate land use(s) associated with each cover type;
- Wildlife sightings should be noted;
- Field verified wetland, riparian, and littoral and shallow water habitats and invasive species occurrences, should be geo-referenced as polygons and overlain on orthophoto at a suitable scale.

Level of Effort/Cost, and Why Alternative Studies will not suffice

In the PAD, First Light identified impacts of the project operations on wetlands, riparian and littoral zone habitat as a potential issue to be addressed in relicensing, and proposed wetland

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

vegetation mapping. However, additional analysis as described above is needed to understand the impacts of the project on these resources and habitats.

A wetlands, riparian, littoral/shallow water, invasive species inventory, of the scope envisioned, would likely require 6-8 months to complete and cost \$40,000 to \$50,000.

Study Request 18: Impacts of the Turners Falls and Northfield Mountain Pump Storage Projects Fish Spawning and Spawning Habitat. (Docket Number p-1889) (Docket Number p-2485)

Goals and Objectives

The goal of this study is to determine if project operations and water level fluctuations in the Turners Falls Project impoundment negatively impact anadromous and resident fish species including but not limited, to sea lamprey, white sucker, fall fish, smallmouth bass, yellow perch, spottail shiners, bluegill, black crappie, chain pickerel, northern pike, common sunfish, and walleye, and if impacts are found to occur, to develop appropriate mitigation measures. This study complements a separate study requests specific to American shad spawning and also on habitats affected by water level manipulations. An additional instream flow study request will address fish habitat effects for species of concern downstream of the Turners Falls Dam.

Specific objectives include:

- 1) Conduct field studies in the main stem, tributaries and backwaters of project affected areas to assess timing and location of fish spawning.
- 2) Conduct field studies in the main stem, tributaries and backwaters of project affected areas to evaluate potential impacts of impoundment fluctuation on nest abandonment, spawning fish displacement and egg dewatering. The study should also evaluate if changes in impoundment fluctuation range would mitigate for identified impacts and if other mitigative measures would lessen these impacts.

A second year of study may be required should river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period (end of March through mid July). Similarly, water temperatures should be closely considered, to ensure representative conditions occurred to reduce bias in observations.

Resource Management Goals

The Service has identified its mission as: working with others to conserve, protect, and enhance fish, wildlife, and plants and their habitats for the continuing benefit of the American people. The Service has identified the following Northeast Regional goals to support the Service's mission and vision, the national Fisheries Program mission, and Service priorities:

- 1) Conservation, and management of aquatic species: Maintain, restore, and recover populations of species of conservation and management concern to self-sustaining levels;
- 2) Conservation and management of aquatic ecosystems: Maintain and restore the ecological

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

composition, structure, and function of natural and modified ecosystems to ensure the long-term sustainability of populations of species of conservation and management concern.

A mission of both the New Hampshire Fish and Game Department and the Massachusetts Division of Fisheries and Wildlife is to protect and conserve fish and their habitats. Resident fish species are an important component of the river's ecology and in some cases are the basis for a sport fishery. This requested study will help protect and conserve resident fish species by ensuring Project operations do not negatively impact their spawning success and spawning habitats.

Public Interest

The requestor is a resource agency.

Existing Information

To our knowledge, no information exists related to this requested study. The Massachusetts Integrated List of Waters shows the Project Area from the VT/NH state line to the Turners Falls Dam impaired due to "other flow regime alterations."

Nexus to Project Operations and Effects

Project operations have the potential to impact fish species by influencing spawning success and spawning habitat quality and quantity. For example, water level changes due to Project operations could create conditions where fish eggs are exposed to air, where spawning habitat is dewatered, and/or where fish abandon nests containing eggs.

Methodology Consistent with Accepted Practice

Common tools to evaluate fish spawning would be used including visual observations of habitats and sampled fish (i.e., in spawning condition, coloration, gonads mature, and other external features that become developed with spawning) collected by gears such as electrofishing, seining and other net gears during defined environmental and or time windows for spawning activity. Project operation impacted areas, should be quantified to identify and define areas subject to dewatering and mapped relative to observations of fish nests, spawning fish, egg deposits. During identified spawning periods for these species, suitable spawning habitats subjected to daily project operational fluctuations will be surveyed to document the type and extent of project effects on nests or spawning habitat (fall fish nests, lamprey nests, bass and sunfish nests, white sucker eggs/larvae) and observable eggs or larvae, relative to water level and other environmental condition, including water temperature and water velocity in noted areas.

Level of Effort/Cost, and Why Alternative Studies will not suffice

FirstLight Power does not propose any studies to meet this need. Estimated cost for the study is moderate.

Study Request 19: In-stream Flow Habitat Assessment Downstream of Cabot Station (Docket Number p-1889)

Conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species. The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species and benthic invertebrate communities. Target fish species include: federally endangered shortnose sturgeon, American shad, fallfish, and white sucker

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Goals and Objectives

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources from the Cabot tailrace of the Turners Falls Project downstream to the Rt. 116 bridge in Sunderland, MA. Specifically, the objective of the study is to conduct an instream flow habitat study to assess the impacts of a range of flows on the wetted area and optimal habitat for key species, including the impacts of hydropeaking flow fluctuations on the quantity and location of aquatic habitat.

The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species and benthic invertebrate communities. Target fish species include: federally endangered shortnose sturgeon, American shad, fallfish, white sucker and walleye.

For shortnose sturgeon, the flow study will need to evaluate bottom velocities in shortnose sturgeon spawning and rearing areas during discharge conditions normally observed from April 15th to June 22nd. Protection of shortnose sturgeon spawning will necessitate establishment of discharges that create bottom velocities suitable for shortnose sturgeon spawning and rearing over a sustained period of time and avoid dramatically fluctuating flows. To protect shortnose sturgeon rearing, adequate discharge without dramatic flow fluctuations are needed to ensure the rearing shoals are wetted and velocities are sufficiently protective for early life stage (ELS) rearing.

Field verification will be necessary to confirm the flow modeling results that identify the flows needed to provide sustained bottom velocities for spawning also maintain flows, depths, and water release regime adequate for spawning and rearing. Velocity and depth data should be collected under each potential operation scenarios such that actual velocity, depth, and flow conditions occurring across the entire spawning and rearing areas including wetted shoals.

Resource Management Goals

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to aquatic resources, the Service's goals are:

- Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Provide an instream flow regime that meets the life history requirements of resident and migratory fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

- Minimize current and potential negative project operation effects on water quality and aquatic habitat.

- Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing at the Cabot Station spawning and rearing site.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requestor is a fish and wildlife resource agency.

Existing Information

Presently FirstLight is required to release 1,433 cfs below the Project. Information included in the PAD does not provide a detailed description of how this minimum flow was established and the Service is not aware of any previously conducted studies that evaluated the adequacy of this minimum flow in protecting aquatic resources in the 10+ miles of riverine habitat below the Cabot Station. Therefore, in order to fill this important information gap, an empirical study is needed to provide information on the relationship between flow and habitat in the Connecticut River downstream of the Cabot tailrace. Results will be used by the Service to determine an appropriate flow recommendation.

Kynard et al. (2012, chapter 3) examined the effects of water manipulation at the Turners Falls project on shortnose sturgeon spawning over the course of 17 years. This body of data represents the best available scientific information which does not support 1,433 cfs as an adequate minimum flow to support successful shortnose sturgeon spawning at Cabot Station. Peaking operations at Cabot Station cause discharge fluctuations to rapidly change bottom velocities from 0.4 m/s to 1/3 m/s over 30 minutes (Kynard et al. 2012, chapter 3). Shortnose sturgeon have not evolved to adapt to such artificial rapid changes in velocities and therefore continue to spawn during fluctuations even though conditions may be unsuitable and likely result in high egg mortality. During the 10 years when spawning succeeded at Cabot Station, discharge flow decreased to less than 35,460 cfs by April 29th. The lowest discharge level observed while females remained on the spawning site was 4,700 cfs. Spawning behavior was not monitored during Cabot Station discharges at or below 3,500 cfs, so it is unclear what the minimum flow threshold is for spawning at Cabot Station. When peaking generation discharges cease during naturally low flow years, the tailrace shoals, likely used by shortnose ELS for rearing, were exposed (observed during years '95, '98-99, '04) and may have resulted in larvae mortality due to stranding and exposure (Kynard et al 2012, chapter 3). Researchers observed that shoal exposure began when river flow below Cabot Station dropped below 7,062 cfs (Kynard and Kieffer 2007). Thus, total flow at Cabot, which may include flow from the Turners Falls Dam or Station 1, must be at least 7,062 cfs to both support adequate bottom velocities and prevent shoal exposure.

Furthermore, the emergency water control gates at Cabot Station that are used to sluice trash from the canal and balance canal flows spill large amounts of water. These large spill events create a plume of turbid turbulent flow, which caused some females to leave the area. These spill events scour bottom sediments which are then carried downstream over the spawning and rearing shoals where an entire year class of early life stages may be destroyed (Kynard et al. 2012, chapter 3). Information included in the PAD does not address adequate flows for

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

shortnose sturgeon spawning and rearing. Results of the requested modeling will be used by the Services to determine an appropriate flow recommendation.

Researchers have also looked at suitable depth and velocity habitat for spawning (Kieffer and Kynard 1996, Kynard et al. 2012, chapter 3). Spawning sites are characterized by moderate river flows with average bottom velocities between 0.4 and 0.8 m/s (Hall et al. 1991, Kieffer and Kynard 1996, NMFS 1998). Water depth at the spawning site appears to be a less important habitat feature than substrate type and flow. A recent study by Kynard et al. (2012, chapter 6) demonstrated that females in an artificial stream will readily accept a shallow water depth of 0.6 m, with a rubble bottom, and 0.3–1.2 m/s bottom velocity. In addition, although eggs and embryos can likely tolerate very low depths, researchers measuring water depths between Turners Falls Dam and Cabot Station in order to recommend minimum flows suitable for an escape route for shortnose sturgeon trapped in the Turners Falls Dam Plunge Pool used a minimum depth of 1.5 x adult body depth. Because adults spawning in an artificial spawning channel frequently positioned themselves on top of one another (Kynard et al. 2012 Chapter 6), a minimum depth to facilitate spawning within the known Cabot Station spawning area is 3.0 body depths, or 19.2 inches.

Nexus to Project Operations and Effects

The Project is currently operated with a minimum flow release that was not based on biological criteria or field study. Further, the project generates power in a peaking mode resulting in significant with-in day flow fluctuations between the minimum and project capacity on hourly or daily basis. The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project (Cushman 1985, Blinn 1995, Freeman et al. 2001). There are more than ten miles of lotic habitat below the project's discharge that are impacted by peaking operations at Cabot Station. This section of the Connecticut River contains habitat that supports native riverine species, including important spawning and rearing habitat for migratory fish such as American shad and federally endangered shortnose sturgeon. Shortnose sturgeon larval migrants initially become bottom dwellers and transition from living off of yolk sacs to orally feeding, which is a critical stage in their life history. While the existing license does require a continuous flow of 1,433 cfs below the project (0.20 cubic feet per second flow per square mile of drainage area - cfs/m), that is equal to only 40% of the Aquatic Base Flow¹. this flow does not sufficiently protect the aquatic resources, including endangered species, in this substantial reach of river, especially in the context of the magnitude, frequency, and duration of changes in habitat that likely occur between minimum and generation flows.

Results of the flow study will be used by the Service to determine an appropriate flow recommendation that will protect and/or enhance the aquatic resources below the Project.

Methodology Consistent with Accepted Practice

In-stream flow habitat assessments are commonly employed in developing plant operational regimes that will reduce impacts or enhance habitat conditions downstream of hydroelectric projects.

The Service requests a flow study be conducted at the Project. Given the length of the river reach (10+ miles) impacted by project operations, we believe a study methodology that utilizes an IFIM approach is appropriate for this site. This same protocol was used during the

¹ The Aquatic Base Flow equates to the August Median Flow as determined using unregulated hydrography or on drainage area at the project site (0.5 cfs per square mile of drainage area) if unregulated hydrography is unavailable.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM
relicensing of the Housatonic River Project (FERC No. 2576),² and has been accepted by the Commission in other licensing proceedings³.

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data along transects located in the reach of river below Cabot Station. The measurements should be taken over a range of test flows. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon HSI curves) of each test flow for target species identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the river channel downstream from the railroad bridge below the mouth of the Deerfield River. The area from the Cabot Station discharge to the railroad bridge should be modeled using 2 dimensional 2D modeling to better characterize flows and velocities in this complex channel area.

The types of data collected with this study should be sufficient to perform a dual-flow analysis and habitat time series or similar approaches that will permit assessment of how quality and location of habitat for target species changes over a range of flows between existing minimum flow and maximum project generation flows.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Field work for instream flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

Study Request 20: In-stream Flow Habitat Assessment of the Turners Falls Bypassed Reach (Docket Number p-1889)**(1) Goals and Objectives**

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources in the bypassed reach between Turners Falls Dam and the Cabot Station discharge. Specifically, the objective of the study is to conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species.

Target fish species include: federally endangered shortnose sturgeon, American shad, fallfish, white sucker, freshwater mussels and benthic macroinvertebrates.

(2) Relevant Resource Management Goals

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to aquatic resources within the Turners Falls bypassed reach, the Service's goals are:

1. Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
2. Provide a flow regime in the bypassed reach that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels), federally listed species, and diadromous fishes.
3. Minimize the current negative effects of project operations on shortnose sturgeon spawning and rearing within known spawning areas of the bypassed natural river reach (i.e., the Rock Dam).
4. Minimize current and potential negative project operation effects on water quality and aquatic habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 et seq.), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 et seq.), and the Federal Power Act (16 U.S.C. §791a, et seq.).

(4) Background and Existing Information

The Turners Falls Project bypasses a 2.7 mile-long section of the Connecticut River. Presently the only required spill releases from the Turners Falls dam to the bypassed reach are 400 cfs from May 1 through July 15 and 120 cfs from July 16 until the river temperature reaches 7°C.

In addition to these flows provided at the Turners Falls Dam, the bypassed reach receives flow from one small tributary (the Fall River, drainage area of 34.2 square miles), which enters the mainstem approximately 0.16 miles below the dam. The bypassed reach also receives the discharge from Station 1, when it is generating (typically when there is flow in excess of Cabot Station's needs). This discharge enters the bypassed reach approximately 0.9 miles below the dam.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Available information in the PAD does not indicate how project operations have altered downstream hydrology, habitat quantity and quality, and water quality, which may affect resident and migratory fish, macroinvertebrates, listed species, aquatic plants and other biota and natural processes in the Connecticut River from below the Turners Falls Dam downstream to the Cabot Station discharge. The PAD also provides no detailed description of the physical or biological characteristics of the bypassed reach.

Limited information exists on the adequacy of the existing bypass flow regime to protect water quality and aquatic life. However, there is existing information (not included in the PAD) relative to minimum flows necessary for shortnose sturgeon spawning and rearing at the Rock Dam spawning site (Kynard et al. 2012). Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period of April 27th through May 22 (Kynard et al. 2012, chapter 3). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 ELS captured, and the longest spawning period of 17 days) even though no spawning was detected at Rock Dam (Kynard et al. 2012, chapter 3). Discharges in 1995 at Rock dam had dropped below 2,500 cfs by March 26th (Kynard et al. 2012, chapter 3), which may indicate the need to have mitigated flow well in advance of spawning. Flow reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning site and not return even if flow later increased to acceptable levels. Researchers observed that the rubble substrates remained dominant during fluctuating flows and cessation of spawning is likely due to velocities falling outside the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kynard et al. 2012, chapter 3). These data represent the best available scientific information and does not support current minimum flow thresholds at the project.

An empirical study is needed to provide information on the relationship between flow and habitat in the bypassed reach for the Service to use in determining a flow recommendation.

(5) Project Nexus

The Project includes a 2.7 mile-long bypassed reach. The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (200 cfs starting on May 1, increasing to 400 cfs when fish passage starts through to July 15, then reduced down to 120 cfs until river temperature drops below 7°C). The 400 cfs release is primarily to facilitate upstream movement of anadromous migrants to the spillway fish ladder at Turners Falls Dam and the 120 cfs was intended to provide protection to shortnose sturgeon by maintaining a wetted habitat 1.5 times the maximum adult body depth through connections between pools within the bypassed reach. Neither of the currently required flows were based on quantitative, rigorous scientific studies.

This section of the Connecticut River contains habitat that supports native riverine species, including important spawning and rearing habitat for the federally endangered shortnose sturgeon. While the existing license does require seasonally-varying flow releases from the Turners Falls dam, we do not believe these flows sufficiently protect the aquatic resources, including endangered species, inhabiting the bypassed reach.

Results of the flow study will be used by the Service to determine an appropriate flow recommendation that will protect and/or enhance the aquatic resources in the bypassed reach for the duration of any new license issued by the Commission.

(6) Proposed methodology

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

The Service requests a bypass flow study be conducted at the Project. Bypass flow habitat assessments are commonly employed in developing flow release protocols that will reduce impacts or enhance habitat conditions in reaches of river bypassed by hydroelectric projects. Given the size of the bypassed reach (2.7 miles long) and the important resources known to inhabit the reach (i.e., federally endangered shortnose sturgeon and diadromous fishes), we believe a study methodology that utilizes an IFIM approach is appropriate for this site. This same protocol was used during the relicensing of the Housatonic River Project (FERC No. 2576), and has been accepted by the Commission in other licensing proceedings .

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data within a range of discharge levels along transects located in the reach of river between the dam and the Cabot Station discharge. The measurements should be taken over a range of test flows up to 6,300 cfs or over a sufficient range of flows to model flows up to 6,300 cfs. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon HSI curves) of each test flow for target species/life stages identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the bypassed reach from the area downstream of the spillway where the river channel constricts to Rawson's Island upstream from the Rock Dam. The area from Rawson Island to the Cabot station discharge should be modeled using 2 dimensional 2D modeling to better characterize flows and velocities in this complex channel area. Likewise, we recommend 2D modeling in the spillway area and mouth of the Falls River to the point where the channel constricts given this complex area with numerous potential flow discharge locations.

The flow study should incorporate the identified minimum flow and temporal parameters for shortnose sturgeon discussed in the Background and Existing Information section of this request.

(7) Level of effort and cost

Field work for flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. Field work associated with this study could be done in conjunction with the below-project instream flow study request. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects (e.g., the Glendale Project, FERC No. 2801).

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Study Request 21: Impact of Project Operations on Downstream Migration of Juvenile American Shad (Docket Number p-1889) (Docket Number p-2485)

Conduct a field study of juvenile American shad outmigration in the Turners Falls impoundment and the power canal and at Turners Falls Dam, Station #1, and Cabot Station to determine if project operations negatively impact juvenile American shad survival and production.

Goals and Objectives

Determine if project operations affect juvenile American shad outmigration survival, recruitment, and production. The following objectives will address this request:

- Assess project operations effects of NMPS and Turners Falls Dam on the timing, orientation, routes, migration rates, and survival of juvenile shad;
- Determine the proportion of juvenile shad that select the Gatehouse into the power canal versus the dam spill gates as a downstream passage route, under varied operational conditions, including a range of spill conditions up to full spill;
- Determine if there are any delays with downstream movement related to either spill via dam gates or through the Gatehouse and within the impoundment due to operations (i.e., NMPS pumping and generation);
- Determine survival rates for juvenile spilled over/through dam gates, under varied operation conditions, including up to full spill during the annual fall power canal outage period;
- Determine the juvenile downstream passage timing and route selection in the power canal to: Station 1; Cabot Station; and the Cabot Station log sluice bypass, and assess delays associated with each of these locations and with project operations (e.g., stockpiling in the canal);
- Based upon year 1 study results on route selection, determine the survival rate for juvenile shad entrained into Station 1; and
- Determine the survival rates for juvenile shad entrained into Cabot Station units;

If it is determined that the Project operations are adversely affecting juvenile shad survival, migration timing, or other deleterious population effects, identify operational solutions or other passage measures that will reduce and minimize these impacts within the project area. This study will require two years of field data to capture inter-annual variability of river discharge, water temperatures, and variability in the timing and abundance of juvenile production and their outmigration timing, which may relate to spring, summer, and fall conditions. This study will compliment the NMPS Fish Entrainment Study Request which includes assessment of impacts to juvenile shad.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
2. Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission *Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management)*, approved in 2010 includes the following objective:

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

1. Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

And recommendation:

1. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

The Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Service's goals are:

1. Minimize current and potential negative project operation effects on juvenile American shad survival, production, and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), Silvio O. Conte National Fish and Wildlife Refuge Act (P.L. 102-212; H.R. 794), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Atlantic States Marine Fisheries Compact (P.L. 539, 77th Congress, as amended by P.L. 721, 81st Congress), and the Atlantic Coastal Fisheries Cooperative Management Act (16 U.S.C. 5107).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the Turners Falls Dam upstream fishways in 1980, American shad have had access to spawning and rearing habitat upstream of Turners Dam. A number of modifications to the Turners Falls fishways have occurred since that time, with the numbers of adult shad passed at Gatehouse Ladder (into Turners Falls Dam impoundment) reaching as much 60,089 in 1992 when a record 721,764 shad passed upstream of Holyoke Dam. However, since 1980 an average of only 3.6 % of the adult shad passed upstream of Holyoke Dam subsequently have passed upstream of Turners Falls Dam, and this value has never exceeded 11%. This value is well below the CRASC 1992 Shad Plan objective of 40-60% passage from the previous dam. In addition, population number and passage numbers past Holyoke have declined substantially, with the average Holyoke passage number over the last 10 years being 211,850. Because historic data suggests that approximately half the returning adult shad to the Connecticut River pass the Holyoke Dam, recent adult returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management restoration goals for the Connecticut River, which extends to the Bellows Falls Dam. In 1990, FirstLight's predecessor, Northeast Utilities, CRASC and its member agencies, signed an MOA on downstream fish passage to address both juvenile and adults at the Turners Falls Project and Northfield Mountain Pumped Storage Project.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

American shad broadcast spawn with the highest spawning activity occurring in runs and lowest activity in pools and riffle/pools (Ross et al. 1993). Field research by Ross et al. (1993) in the Delaware River further noted that a combination of physical characteristics that seems to be avoided by spawning adults is slow current and greater depth. American shad year-class strength has been shown to depend on parent stock size and environmental conditions during the larval life stages (Creeco and Savoy 1984). Delays in juvenile American shad outmigration may affect survival rates in the transition to the marine environment (Zydlewski et al. 2003). One published study on the Connecticut River, identified that juvenile shad outmigration began when declining autumn temperatures reached 19C and peaked at 16C (O'Leary and Kynard 1986).

Juvenile American shad production has been monitored upstream of the Vernon Dam and immediately downstream of that dam by Vermont Yankee Nuclear as part of an annual monitoring program using both boat electrofishing (since 1991) and beach seining (since 2000). Sampling of juvenile shad was also conducted by a contractor hired by Northeast Utilities in the Turners Falls impoundment in 1992. O'Donnell and Letcher (2008) examined juvenile shad early life history and migration upstream and downstream of Turners Falls Dam. Their study results led to the decision by the agencies to require earlier operation of downstream fishways to protect early season juvenile shad out-migrants (1 September prior to 2010, 15 August in 2010, and since 2011, 1 August).

Downstream juvenile clupeid passage studies at Turners Falls were conducted in the fall of 1991 which included the objectives of determining the percentage of juvenile shad and herring that pass via the bypass log sluice or that were entrained in the Cabot Station turbines and related data (e.g., catch rates) were compared. The 1991 Downstream Clupeid Study did not assess survival rates for juveniles for either of these passage routes. The 1991 study report documented a higher rate entrainment into the project turbines (23.0 fish per minute) versus through the bypass sluice (11.6 fish per minute). It was concluded that only an estimated 54% (average bypass rate, weighted by estimated number bypassed) of the juvenile American shad approaching Cabot Station were bypassed via the log sluice. The range of the percent bypassed varied widely by date, between nearly 0 and 83%, with 'no clear explanation as to why.' The report did not identify the percentage entrained into the turbines but it can be reasoned to be substantial based on the data presented in the report or assumed as the remaining balance (46%). as there were no spill events reported during this study, and therefore nowhere else for them to pass. It was further noted that entrainment rates for juveniles were consistently greatest for units 1 and 6 (ends), not uniform across all units. Although no concurrent bypass sampling occurred during the first entrainment sampling events, it was noted that "entrainment rates were relatively high during the end of September." Additional modifications have occurred over time without quantitative evaluation to improve downstream passage attraction and use to the bypass sluice, including lighting systems.

The 1994 Downstream Juvenile Shad Study report assessed juvenile shad survival from passage via the log sluice, reported to be 98%, based on tagged and recaptured fish (held for up to 48 hours). Scale loss (<20%) (22 of treatment fish) compared with scale loss of >20% (5 of treatment fish) was examined and determined to occur in an overall total of 10% of study fish (adjusted by control fish data).

Nexus to Project Operations and Effects

Adult American shad passed upstream of Turners Falls Dam utilize upstream spawning habitat. Juvenile American shad production occurs in these habitats upstream of Turners Falls Dam on an annual basis. Juvenile American shad require safe and timely downstream

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM
passage measures to have the opportunity to contribute to the fishery agencies' target restoration population size.

The Service is not aware of any studies being conducted specifically designed to determine:

- When spill gates are open at the Turners Falls Dam?;
- What proportion of juvenile outmigrant shad take that route of passage?;
- What is the rate of survival under a range of spill and gate configurations?
- What is the timing, duration, and magnitude of juvenile shad outmigrants in summer and fall to the Turners Falls Dam and Gatehouse?
- Are there delays in migration/movement at the dam, Gatehouse, Cabot Station, or Station 1?
- For juveniles that enter the power canal, what proportion subsequently enter the Station 1 power canal?
- As there is no downstream passage facilities at Station #1, and trash rack spacing is 2.6 inches, what is the survival rate of juvenile shad entrained at Station #1?
- What is the rate of movement through the Turners Power Canal, relative to r delay to outmigrant juvenile shad and the potential accumulation of juveniles (e.g., prior to the canal drawdown in September)?
- What proportion of juvenile shad use the downstream sluice bypass versus the Cabot Station turbines under varied operational conditions given that project operations may change (PAD notes possible increase in turbine capacity at Cabot)?
- Based upon earlier facility studies (1991 Downstream Clupeid) a large proportion and number of juvenile shad are entrained into Cabot Station turbines. What are the associated impacts in terms of short-term and longer term survival and injury (i.e., scale loss)?

The Service is concerned that project operations may impact juvenile shad outmigration survival and be contributing to the failure of the Connecticut River shad population to meet management targets. In the PAD, proposed modification include; Station 1 may be upgraded with new turbines, Station 1 may be closed, and/or the turbine capacity at Cabot may be increased. It is unclear how these scenarios will affect the questions identified in this request.

Methodology Consistent with Accepted Practice

The impact to juvenile shad outmigrants by project operations would be best studied by a combination of approaches including hydroacoustic, radio telemetry, and turbine balloon tags. Project discharge over a full range of existing and, to the extent possible, potential future operational conditions at Station 1 and Cabot, at the dam (likely increased bypass reach flows in new license) and in relation to the Gatehouse, should be examined relative to timing, duration, and magnitude of juvenile shad migration to and through these areas, with hydroacoustic equipment for natural/wild fish evaluation. In addition, study fish should be collected and tagged (PIT, radio, other mark, balloon) to also empirically determine rates of survival for fish passed over or through the dam's gates, under varied operations, including up to full spill condition that occurs annually in fall with canal outage period. The understanding of the timing, magnitude, duration of the wild fish outmigration will help inform the design, data/results, and assessment of tagged study fish. The release of tagged or marked fish (radio, PIT) upstream of the Gatehouse induction into the power canal, will provide data on concerns of delay and route selection to Station 1, Cabot Station downstream bypass, Cabot Station spill gates, and Cabot Station turbines. Additional hydroacoustic assessment at Cabot Station forebay will provide information on wild/natural juvenile fish timing, magnitude, and duration to and through this area. Based upon Year 1 study findings relative to the frequency, magnitude, timing of juvenile American shad that end up in the forebay of Station 1, the determination of whether an entrainment survival study at that site is necessary will be made.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Release sites for tagged fish will be determined based upon further consultation among the parties.

Radio tagged juvenile shad will be released in areas upstream of the NMPS facility at multiple release locations, to determine operation effects on migration rates, route, orientation, entrainment, and survival, over a full range of permitted and operational conditions.

Level of Effort/Cost, and Why Alternative Studies will not suffice

First Light does not propose any studies to meet this need. Estimated cost for the study is expected to be high, between \$200,000 and \$300,000, with the majority of costs associated with equipment (hydroacoustic gear, radio tags, radio receivers, and PIT readers) and related fieldwork labor.

Study Request 22: Use of an Ultrasound Array in to Create Avoidance of the Cabot Station Tailrace By Pre-spawned Adult American shad and Facilitate Upstream Movement to the Turners Falls Dam (Docket Number p-1889)

Goals and Objectives

The goal of this study is to determine if use of ultrasound is an effective behavioral mechanism to create avoidance of the Cabot tailrace area by upstream migrating adult shad. If not attracted to the Cabot Station discharge, shad may proceed upstream and pass the Turners Falls Dam via the fishway at the dam.

The objective of the study would be to establish a high frequency sound (ultrasound) array across the entire Cabot Station tailrace and determine the effect of the ensonified field on upstream and downstream migrating radio-tagged shad moving past Cabot Station. This would be accomplished by monitoring the movements and passage of shad and the time shad spend in the tailrace area. If effective, this technology also may be applicable to the Turners Falls #1 Station discharge.

Resource Management Goals

In 1992, the Connecticut River Atlantic Salmon Commission (CRASC) developed a draft document titled: A Management Plan for American Shad in the Connecticut River. Management Objectives in the plan include the following:

1. Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually. (Table 1)
2. Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
3. Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

And recommendations:

Upstream Passage –

1. American shad must be able to locate and enter the passage facility with little effort and without stress.
2. Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
3. Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.

Downstream Passage –

1. To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

Based on the CRASC plan, the Service seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

1. Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
2. Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad movement and migration, the Service's goals are:

1. Minimize current and potential negative project operation effects such as migration delays, false attraction, turbine entrainment, survival of project passage routes, and trashrack impingement, that could hinder management goals and objectives.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 et seq.), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 et seq.), and the Federal Power Act (16 U.S.C. §791a, et seq.), the Atlantic States Marine Fisheries Compact (P.L. 539, 77th Congress, as amended by P.L. 721, 81st Congress), and the Atlantic Coastal Fisheries Cooperative Management Act (16 U.S.C. 5107)..

Public Interest

The requestor is a federal natural resource agency.

Existing Information

The Turners Falls Project has two fish ladders that anadromous migrants must use to pass the project; one at the Cabot Station tailrace and one at the spillway. Both ladders have documented passage problems. Further, fish that are able to successfully swim up the Cabot Station ladder exit into the Cabot Station power canal and must successfully enter and ascend another fish ladder (Gatehouse Fishway) before entering the Turners Falls impoundment and continuing up the Connecticut River. Spillway Ladder fish must also pass the Gatehouse ladder to reach the impoundment. The Gatehouse Fishway also has well documented passage issues.

Many years of study and design changes at the Gatehouse Fishway have improved passage effectiveness of that facility, but overall passage through the Cabot and Gatehouse fishways remains less effective than necessary to achieve management goals. A potential alternative to the current configuration of fishways at the project would be to cease using the Cabot ladder (thereby eliminating problems with that ladder and the need to pass the Gatehouse ladder), and instead operate a single fish lift facility at the spillway. However, for this to be a viable option, one major issue would need to be resolved: false attraction to the Cabot Station tailrace discharge. Therefore, this study would attempt to determine if use of ultrasound technology would be an effective method to minimize false attraction to the tailrace discharge while facilitating movement past the Cabot discharge and up to the spillway area without delay.

Much information exists about adult shad avoidance of ultrasound and the adaptive significance seems related to avoidance of echolocation signals of predator bottlenose dolphins (Mann et al., 1997; 1998). These authors suggest shad can detect the echolocation clicks of dolphins up to 187 meters away. Further, in field trials in the early 1980s to develop a guidance system for downstream-migrants in the First Level Canal of the Holyoke Canal System, adult shad avoided but were not well guided by an ultrasonic array. However, upstream migrants were guided well and even stopped entirely by the ensonified field

20130228-5004 FERC PDF (Unofficial) 2/27/2013 5:00:05 PM

(Kynard and Taylor 1984). Creating an ensonified field caused adult shad to leave their preferred location in the river upstream of trashracks at Holyoke Dam as long as the sound system was on.

Blueback herring also avoided the ultrasound field and behaved similar to shad in the Holyoke Canal studies (Kynard and Taylor 1984). Acoustic barriers have been used for blueback herring on the Savannah River (Richard B. Russell Dam) and Santee River (St. Stephen fish lift) in South Carolina and on the Mohawk River in New York (Crescent Project, FERC No. 4678; Vischer Ferry, FERC No. 4679). Evidence from many studies that attempted to produce behavioral avoidance by adult shad strongly suggests that ultrasound is the most effective stimuli (Carlson and Popper, 1997). Thus, the available evidence suggests that shad (and blueback herring) may be dissuaded from delaying at the tailrace of Cabot Station by installing and operating an ultrasound field.

In addition, one year of study on juvenile shad and blueback herring movements in the Holyoke Canal (Buckley and Kynard 1985) and two years of study in an experimental flume (Kynard et al. 2003) found that juveniles did not exhibit an avoidance response to the same high frequency (162 kHz) that was avoided by adult shad and bluebacks at Holyoke.

Nexus to Project Operations and Effects

Given the poor performance of the upstream passage facilities at Turners Falls, studies to assess potential passage solutions are appropriate areas during relicensing proceedings. This study, coupled with the adult shad radio-telemetry study, can provide the information needed to select the best approach to resolve upstream shad passage at the project.

Methodology Consistent with Accepted Practices

Acoustic barriers have been used for blueback herring on the Savannah River (Richard B. Russell Dam) and Santee River (St. Stephen fish lift) in South Carolina and on the Mohawk River in New York (Crescent Project, FERC No. 4678; Vischer Ferry, FERC No. 4679). This study would establish a high frequency sound (ultrasound) array across the entire Cabot Station tailrace and determine the effect of the ensonified field on upstream and downstream migrating shad moving through Cabot Station by monitoring shad behavior and the time that detected shad spend in the tailrace.

Shad tagged as part of the large-scale shad movement/migration telemetry study would be used to track shad movements through the Cabot Station area with the ultrasound system on versus off. Data would be analyzed to determine if ensonification is a successful deterrent mechanism (e.g., if shad spend less time in the tailrace when the area is ensonified relative to when it is not ensonified and whether shad move past Cabot Station to the spillway with limited delay)

Several businesses sell and operate ultrasound systems for fish avoidance. The use of these systems is world-wide at power production and water control facilities.

Level of Effort/Cost, and Why Alternatives will not suffice

The level of effort/cost for the test will be low to moderate. Costs will be related to rental, installation, and operation of the ultrasound system, analysis of data, and production of a final report. The study could utilize the same test fish and monitoring equipment as the adult shad radiotelemetry study (although a few additional tracking stations may have to be installed in the Cabot Station tailrace).

Study Requests

Dear Secretary Bose:

The Massachusetts Division of Fisheries and Wildlife (Division) is the agency responsible for the protection and management of the fish and wildlife resources of the Commonwealth. The Division is also responsible for the regulatory protection of imperiled species and their habitats as codified under the Massachusetts Endangered Species Act (M.G.L. c.131A). The Massachusetts Endangered Species Act (MESA) was enacted in December 1990. Implementing regulations (321 CMR 10.00) were promulgated in 1992 and recently revised and implemented as of November 2010. The MESA provides a framework for review of projects or activities that occur within mapped areas of the state, called *Priority Habitat*, and published in the Natural Heritage Atlas. As such, we monitor operations at hydroelectric projects within the Commonwealth, as well as comment on proposed hydroelectric facilities. The Division has received your letter dated October 30, 2012, requesting review of the Preliminary Application Document (PAD) for, the Turners Falls Project (FERC No. 1889) and the Northfield Mountain Project (FERC No. 2485), and offers the following comments on the PAD and the Scoping Document 1 (SD1).

PROJECT DESCRIPTION

The Turners Falls Project and Northfield Mountain Pumped Storage Project are located on the Connecticut River within Franklin County, Massachusetts, Windham County, Vermont, and Cheshire County, New Hampshire. The greater portion of the Turners Falls Project and Northfield Mountain Project, including developed facilities and most of the lands within the project boundary, are located in Franklin County, Massachusetts; specifically, in the towns of Erving, Gill, Greenfield, Montague, and Northfield. The northern reaches of the Turners Falls Project and Northfield Mountain Project boundary extend to the base of the Vernon dam in the towns of Hinsdale, New Hampshire, and Vernon, Vermont. The Turners Falls Project has an installed capacity of 67.709 MW and an annual generation of 320,140 MWh. The Northfield Mountain Pumped Storage Project has an installed capacity of 1,119.2 MW and an annual generation of 1,143,038 MWh.

The Turners Falls Project's dam is located at approximately RM 122 on the Connecticut River in the towns of Gill and Montague, Massachusetts. The tailrace of the Northfield Mountain Project is located approximately 5.2 miles upstream of Turners Falls Project's dam, in the town of Northfield, Massachusetts. The upper reservoir of the Northfield Mountain Project is located atop Northfield Mountain in Erving, Massachusetts. The Turners Falls impoundment serves as the lower reservoir for the Northfield Mountain Project.

www.mass.gov/masswildlife

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The Turners Falls dam is located on the Connecticut River at approximately RM 122 in the towns of Gill and Montague, Massachusetts. The dam consists of two individual concrete gravity dams, referred to as the Gill dam and Montague dam, which are connected by a natural rock island known as Great Island. The Montague dam is approximately 35 feet high and 630 feet long, is founded on bedrock and connects Great Island to the west bank of the Connecticut River. The Gill dam is approximately 55 feet high and 493 feet long extending from the Gill shoreline (east bank) to Great Island. The Turners Falls impoundment (which also serves as the lower reservoir for the Northfield Mountain Project), is approximately 20 miles long, extending upstream through the Connecticut River valley to the base of Vernon dam. The impoundment has a surface area of approximately 2,110 acres and a gross storage capacity of 21,500 acre-feet at elevation 185.0 feet msl (as measured at Turners Falls dam) and also serves as the lower reservoir for the Northfield Mountain Pumped Storage Project. Most of the Turners Falls impoundment lies in Massachusetts; however, approximately 5.7 miles of the northern portion of the impoundment are located in New Hampshire and Vermont. At Turners Falls dam, the total drainage area is approximately 7,163 mi², or about 64% of the Connecticut River Basin drainage area (11,250 mi²). The project includes two powerhouses, Station No. 1 and Cabot Station, which together have an authorized installed capacity of 67.709 MW which generated an average of 320,140 MWh annually from 2000-2009. Station No. 1 contains seven turbine/generators of which five are currently operational. Station No. 1 generating units consist of single runner vertical Francis turbines. The approximate turbine and hydraulic capacities of each unit are as follows: 2,100hp/560 cfs for Unit 1; 590hp/140 cfs for Unit 2; 1,900hp/500 cfs for Unit 3; Unit 4 is non-operational; 1,635hp/490 cfs for Unit 5; Unit 6 is non-operational; and 1,955hp/520 cfs for Unit 7. Cabot Station generating units consist of six vertical single runner Francis turbines. The approximate turbine and hydraulic capacities of each of the Cabot unit are 13,867hp/2,288 cfs.

The tailrace of the Northfield Mountain Project is located approximately 5.2 miles upstream of Turners Falls dam, in the town of Northfield, Massachusetts, and in the Turners Falls impoundment. The upper reservoir of the Northfield Mountain Project is located atop Northfield Mountain in Erving, Massachusetts and consists of a main dam, rockfill dikes and a concrete gravity dam. The upper reservoir typically operates between elevations 1,000.5 feet msl and 938 msl which provides a 62.5 foot drawdown. Within this range of fluctuation, the upper reservoir has a surface area of 134 and 286 acres at elevations 938 and 1,000 feet msl, respectively, and approximately 12,318 acre-feet of usable storage. The underground powerhouse contains four reversible pump/turbines that operate at gross heads ranging from 753 to 824.5 msl. The project has an authorized installed capacity of 1,119.2 MW (Unit 1: 267.9 MW, Unit 2: 291.7 MW, Unit 3: 291.7 MW and Unit 4: 267.9 MW). The approximate station hydraulic capacity is 15,200 cfs (3,800 cfs per/pump) in pumping mode and 20,000 cfs (5,000 cfs per/turbine) in a generation mode.

PROPOSAL

The current FERC licenses for the Turners Falls Project and Northfield Mountain Project expire on April 30, 2018. The owner of these projects, FirstLight Hydro Generating Company (FirstLight), a subsidiary of IPR-GDF SUEZ North America, Inc., is applying to relicense the projects. FirstLight is proposing to evaluate potential modifications to the Turners Falls Project and Northfield Mountain Project at this time. The potential modifications that FirstLight is evaluating include the following:

- Upgrading Station No. 1 with new or rehabilitated turbines.
- Closing Station No. 1 and adding a turbine generator at Cabot of similar hydraulic capacity to Station No. 1's.
- Utilizing the full hydraulic capacity of the Cabot turbines including currently unused capacity.
- Utilizing more storage in the Northfield Mountain Project's upper reservoir.
- Increasing the unit and station capacity at the Northfield Mountain Project.

COMMENTS

Scoping Document 1

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

2.1 2.1

Purposes of Scoping

“Scoping is the process used to identify issues, concerns, and opportunities for enhancement or mitigation associated with a proposed action.” This is a difficult mandate given that we have no idea which (if any) of the potential project modifications listed in the SD1 and PAD the project owner will propose.

3.4.2.4

Water Resources

Reservoir Drawdown. How will the proposed changes to project operations affect the current practice of limiting reservoir drawdown to 3.7 feet rather than the 9 feet allowed by the current license?

Aquatic Resources

Fishways: The Division believes that the project’s fishways do not provide adequate fish passage particularly for American Shad. Studies conducted over the last few years as well as studies that the Division is now proposing should allow the FERC to determine what will be required to remedy this situation. Upstream and downstream passage for American eel must also be addressed.

Minimum Flow: The Division believes that the current minimum flow provided to the project’s bypass reach is insufficient to protect aquatic life in that reach. The project owner is proposing a study to help determine a more appropriate flow. The Division has been consulting on the design of this study and believes that the FERC should allow this study to commence this summer (2013).

3.4.2.5

Aquatic Resources

The Division is concerned about the magnitude and potential effects of entrainment of fish, particularly juvenile American shad by the Northfield Mt project and has proposed studies to address this concern.

Terrestrial Resources

Bennett Meadow Wildlife Management Area

Approximately 200 acres, mostly alluvial floodplain, of Northfield Mountain project land which is presently leased to local farmers for agricultural use. The area is open to the public and managed by the Division as a wildlife management area. Hunting and fishing is permitted. Crop production plus existing wetlands, forest cover and river frontage provide excellent wildlife habitat. Bennett Brook feeds an extensive beaver flowage and a slough which create excellent habitat for waterfowl. The Division presently stocks pheasants on the Bennett Meadow property and has considered stocking fish in Bennett Brook.

Bennett Meadows was to be transferred to Massachusetts Division of Fisheries and Wildlife ownership as part of the original FERC licensing of the Northfield Mountain Project. The very similar 161 acre Pauchaug Brook Wildlife Management Area was transferred from the project owner to the Division at that time. The Division has been actively involved with the management of the Bennett Meadow Wildlife Management Area throughout the term of the current license and is still very interested in obtaining ownership of this land. The Division asks that the Project owner and the FERC consider this.

4.0

Cumulative effects

Because the five Connecticut River Projects are located contiguously on the main stem Connecticut River between RM 262 and RM 122 the Division believes that many of the project effects should be considered cumulative. In addition to those already identified by FERC staff the Division believes the following issues need to be addressed.

4.3.3

Aquatic Resources

Because delays to migration at one project may lead to a diminished chance to pass subsequent projects the Division believes that effects of project facilities and operations, (including reservoir fluctuations, and generation releases) on fish migration through and within project fishways, reservoirs, and the downstream riverine corridor should be studies cumulatively.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

5.0 and 6.0 Proposed Studies and Requests for Studies

In addition to the list of studies proposed by the project owner, the Division has proposed specific studies which are attached to this letter.

Requested studies

1. In-stream Flow Habitat Assessment of the Turners Falls Bypassed Reach
2. In-stream Flow Habitat Assessment Downstream of Cabot Station
3. Telemetry Study of Upstream and Downstream Migrating Adult American Shad to Assess Passage Routes, Effectiveness, Delays, and Survival
4. Impact of Project Operations on Shad Spawning, Spawning Habitat, and Egg Deposition in the Project Area.
5. Shad Population Model for the Connecticut River
6. Impact of Project Operations on Downstream Migration of Juvenile American Shad
7. Upstream American Eel Passage Assessment at Turners Falls
8. Downstream American Eel Passage Assessment at Turners Falls and Northfield Mountain
9. Evaluation of Timing of Downstream Migratory Movements of American Eels on the Mainstem Connecticut River
10. Three-dimensional Computational Fluid Dynamics (CFD) Modeling in the Vicinity of Fishway Entrances and Powerhouse Forebays
11. Model flows in the Northfield Mountain Pumped Storage Project discharge tailrace using two-dimensional Computational Fluid Dynamics (CFD) model techniques
12. Entrainment of Migratory and Riverine Fish from the Connecticut River into the Northfield Mountain Pump Storage Project
13. Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations
14. Impacts of the Turners Falls and Northfield Mountain Pumped Storage Project Operations on Tributary and Backwater Area Access and Habitats
15. Impacts of the Turners Falls and Northfield Mountain Pumped Storage Projects on Littoral Zone Fish Habitat and Spawning
16. Impacts of Turners Falls Canal Drawdown on Fish Migration and Aquatic Organism Populations
17. Climate Change as it Relates to Continued Operation of the Northfield Mountain Pumped Storage, and Turners Falls Projects
18. Climate Change as it Relates to Continued Operation of the Northfield Mountain Pumped Storage, and Turners Falls Projects
19. Integrate Modeled River Flows and Water Levels with Habitat Assessment for State-listed Riparian Invertebrate Species
20. Habitat Assessment, Surveys, and Modeling of Suitable Habitat for State-listed Mussel Species in the Connecticut River
21. Fish Assemblage Assessment and Glochidia Surveys in the Connecticut River
22. Assessing Operational Impacts on Emergence of State-listed Odonates in the Connecticut River and Northfield Mountain Upper Reservoir
23. Assessing Operational Impacts on State-listed Rare Plants in the Connecticut River

9.0 Comprehensive Plans

In 2006, the Massachusetts Division of Fisheries and Wildlife received approval for its State Wildlife Conservation Strategy, most often referred to as the State Wildlife Action Plan (SWAP). The SWAP is a comprehensive document that will help guide wildlife conservation decision making for Massachusetts' wildlife for many years. The Massachusetts Action Plan represents an important effort by the Division to engage the public in a dialogue about the future of our wildlife resources. During development of the Massachusetts Plan, we sought public input and comment through presentations of a draft to the Fisheries and Wildlife Board, the Natural Heritage and Endangered Species Advisory Committee, and the Massachusetts Teaming With Wildlife Coalition. In addition, the Fisheries and Wildlife Board held a public informational hearing. A draft copy of the Plan was posted prominently on the agency website for public comment. At least 4300 entities were directly notified of this website posting through the Division's newsletter, including media outlets, conservation organizations, sportsmen and other private citizens. As a

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

result, we received over 600 website visits to the Plan. The final Plan incorporated public comments and was reposted on the website for further public review prior to formal submission to the US Fish and Wildlife Division.

The Plan includes:

- A brief history of the Division and past successful efforts to conserve the biodiversity of the Commonwealth.
- A review of the landscape changes which have affected wildlife populations and sets the stage for problems we see facing these species today.
- An explanation of the process used to identify the habitats and species in the greatest need of conservation. Identifies the primary strategies needed to conserve these species and their habitats
- An recognition of the need to monitor these efforts as strategies are implemented both to ensure that time and money are providing the expected results and to determine if changing conditions require a change in strategy.

Massachusetts' Plan is organized around 22 habitat types and 257 wildlife species in greatest need of conservation. The habitat types range from large-scale habitats such as Upland Forests; to medium-scale habitats like Grasslands, to small-scale habitats such as Vernal Pools. Information for each habitat type includes

- habitat description;
- the suite of species in associated with that habitat;
- the problems and threats faced by them;
- a map showing the distribution of the habitat type across the state, when available;
- a listing of the conservation strategies needed to conserve the habitat; and
- monitoring requirements that will ensure the success of the conservation strategies.

There is also information about the 257 wildlife species in greatest need of conservation occurring in one or more of the above 22 habitat types including:

- Conservation status ranking and habitat association
- Species Life History
- State distribution and abundance
- Habitat requirement
- Conservation threats

The Division has requested that FERC add the MA SWAP to the list of Comprehensive Plans in a separate filing on February 13, 2013.

Preliminary Application Document

General

The PAD is very thorough and provides a higher level of detail than we see in most applications.

Specific

Section 4.14: Tributary Streams. The Fall River which enters the project bypass reach just below the Turners falls Dam is not listed.

Figure 4.1-2: Connecticut River Subbasins, Tributaries, and Dams. Several Hydroelectric dams are not depicted in this figure. The Crescent Street Dam on the Millers River is located between the two projects that are depicted. There are three hydroelectric projects on the Westfield River in Russell- the figure depicts only one project in this location. The figure does not depict the two large USACE flood control dams on the Westfield River, Knightville on the East Branch and Littleville on the Middle Branch. There are a number of hydroelectric dams on the Chicopee that are not depicted. Starting at the Connecticut River they are: Dwight, Chicopee Falls, Indian Orchard, Putts Bridge, Collins, and Red Bridge.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

4.4.5.2: American Shad. Timing of outmigration of YOY is cited as September. New studies have shown that YOY shad in the CT River move all summer long¹.

4.4.5.2: Blueback Herring. Blueback Herring were known to spawn in the Fall River- a tributary to the Turners Falls project bypass reach.

Figure 4.4.5-2: Annual Number of Blueback Herring Passed into the Holyoke Impoundment below the Turners Falls Project, 1980-2012. Perhaps the use of a log scale would be better suited to the wide range of data depicted.

Section 5.4 Relevant Qualifying Resource Management Plans

In 2006, the Massachusetts Division of Fisheries and Wildlife received approval for its State Wildlife Conservation Strategy, most often referred to as the State Wildlife Action Plan (SWAP). The SWAP is a comprehensive document that will help guide wildlife conservation decision making for Massachusetts' wildlife for many years. The Massachusetts Action Plan represents an important effort by the Division to engage the public in a dialogue about the future of our wildlife resources. During development of the Massachusetts Plan, we sought public input and comment through presentations of a draft to the Fisheries and Wildlife Board, the Natural Heritage and Endangered Species Advisory Committee, and the Massachusetts Teaming With Wildlife Coalition. In addition, the Fisheries and Wildlife Board held a public informational hearing. A draft copy of the Plan was posted prominently on the agency website for public comment. At least 4300 entities were directly notified of this website posting through the Division's newsletter, including media outlets, conservation organizations, sportsmen and other private citizens. As a result, we received over 600 website visits to the Plan. The final Plan incorporated public comments and was reposted on the website for further public review prior to formal submission to the US Fish and Wildlife Division.

The Plan includes:

- A brief history of the Division and past successful efforts to conserve the biodiversity of the Commonwealth.
- A review of the landscape changes which have affected wildlife populations and sets the stage for problems we see facing these species today.
- An explanation of the process used to identify the habitats and species in the greatest need of conservation. Identifies the primary strategies needed to conserve these species and their habitats
- An recognition of the need to monitor these efforts as strategies are implemented both to ensure that time and money are providing the expected results and to determine if changing conditions require a change in strategy.

Massachusetts' Plan is organized around 22 habitat types and 257 wildlife species in greatest need of conservation. The habitat types range from large-scale habitats such as Upland Forests; to medium-scale habitats like Grasslands, to small-scale habitats such as Vernal Pools. Information for each habitat type includes

- habitat description;
- the suite of species in associated with that habitat;
- the problems and threats faced by them;
- a map showing the distribution of the habitat type across the state, when available;
- a listing of the conservation strategies needed to conserve the habitat; and
- monitoring requirements that will ensure the success of the conservation strategies.

There is also information about the 257 wildlife species in greatest need of conservation occurring in one or more of the above 22 habitat types including:

- Conservation status ranking and habitat association
- Species Life History
- State distribution and abundance
- Habitat requirement

Requested Study No. 1.
In-stream Flow Habitat Assessment of the Turners Falls Bypassed Reach

Goals and Objectives

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources in the bypassed reach between Turners Falls Dam and the Cabot Station discharge. Specifically, the objective of the study is to conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species.

Target fish species include: State listed (endangered) Shortnose sturgeon, American shad, fallfish, white sucker, freshwater mussels and benthic macroinvertebrates.

Relevant Resource Management Goals

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to aquatic resources within the Turners Falls bypassed reach, the Division's goals are:

- Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Provide a flow regime in the bypassed reach that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels), state listed species, and diadromous fishes.
- Minimize the current negative effects of project operations on shortnose sturgeon spawning and rearing within known spawning areas of the bypassed natural river reach (i.e., the Rock Dam).
- Minimize current and potential negative project operation effects on water quality and aquatic habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Background and Existing Information

The Turners Falls Project bypasses a 2.7 mile-long section of the Connecticut River. Presently the only required spill releases from the Turners Falls dam to the bypassed reach are 400 cfs from May 1 through July 15 and 120 cfs from July 16 until the river temperature reaches 7°C.

In addition to these flows provided at the Turners Falls Dam, the bypassed reach receives flow from one small tributary (the Fall River, drainage area of 34.2 square miles), which enters the mainstem approximately 0.16 miles below the dam. The bypassed reach also receives the discharge from Station 1, when it is generating (typically when there is flow in excess of Cabot Station's needs). This discharge enters the bypassed reach approximately 0.9 miles below the dam.

Available information in the PAD does not indicate how project operations have altered downstream hydrology, habitat quantity and quality, and water quality, which may affect resident and migratory fish, macroinvertebrates, listed species, aquatic plants and other biota and natural processes in the Connecticut River from below the Turners

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Falls Dam downstream to the Cabot Station discharge. The PAD also provides no detailed description of the physical or biological characteristics of the bypassed reach.

Limited information exists on the adequacy of the existing bypass flow regime to protect water quality and aquatic life. However, there is existing information (not included in the PAD) relative to minimum flows necessary for shortnose sturgeon spawning and rearing at the Rock Dam spawning site (Kynard et al. 2012). Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period of April 27 through May 22 (Kynard et al. 2012, chapter 3). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 early life stage captured, and the longest spawning period of 17 days) even though no spawning was detected at Rock Dam (Kynard et al. 2012, chapter 3). Discharges in 1995 at Rock dam had dropped below 2,500 cfs by March 26th (Kynard et al. 2012, chapter 3), which may indicate the need to have mitigated flow well in advance of spawning. Flow reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning site and not return even if flow later increased to acceptable levels. Researchers observed that the rubble substrates remained dominant during fluctuating flows and cessation of spawning is likely due to velocities falling outside the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kynard et al. 2012, chapter 3). These data represent the best available scientific information and does not support current minimum flow thresholds at the project.

An empirical study is needed to provide information on the relationship between flow and habitat in the bypassed reach for the Division to use in determining a flow recommendation.

Nexus to Project

The Project includes a 2.7 mile-long bypassed reach. The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (200 cfs starting on May 1, increasing to 400 cfs when fish passage starts through to July 15, then reduced down to 120 cfs until river temperature drops below 7°C). The 400 cfs release is primarily to facilitate upstream movement of anadromous migrants to the spillway fish ladder at Turners Falls Dam and the 120 cfs was intended to provide protection to shortnose sturgeon by maintaining a wetted habitat 1.5 times the maximum adult body depth through connections between pools within the bypassed reach. Neither of the currently required flows were based on quantitative, rigorous scientific studies.

This section of the Connecticut River contains habitat that supports native riverine species, including important spawning and rearing habitat for the state endangered shortnose sturgeon. While the existing license does require seasonally-varying flow releases from the Turners Falls dam, we do not believe these flows sufficiently protect the aquatic resources, including endangered species, inhabiting the bypassed reach.

Results of the flow study will be used by the Division to determine an appropriate flow recommendation that will protect and/or enhance the aquatic resources in the bypassed reach for the duration of any new license issued by the Commission.

Proposed methodology

The Division requests a bypass flow study be conducted at the Project. Bypass flow habitat assessments are commonly employed in developing flow release protocols that will reduce impacts or enhance habitat conditions in reaches of river bypassed by hydroelectric projects.

Given the size of the bypassed reach (2.7 miles long) and the important resources known to inhabit the reach (i.e., state endangered shortnose sturgeon and diadromous fishes), we believe a study methodology that utilizes an IFIM approach is appropriate for this site. This same protocol was used during the relicensing of the Housatonic River Project (FERC No. 2576),² and has been accepted by the Commission in other licensing proceedings³.

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data within a range of discharge levels along transects located in the reach of river between the dam and the Cabot Station discharge. The measurements should be taken over a range of test flows up to 6,300 cfs or over a sufficient

³ Glendale Project (FERC No. 2801) Final Bypass Reach Aquatic Habitat and Instream Flow Study in Glendale Hydroelectric Project Application for Subsequent License (FERC No. 2801), Volume 2, Appendix B, pages 7-8, October 2007.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

range of flows to model flows up to 6,300 cfs. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon HSI curves) of each test flow for target species/life stages identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the bypassed reach from the area downstream of the spillway where the river channel constricts to Rawsons Island upstream from the Rock Dam. The area from Rawson Island to the Cabot station discharge should be modeled using 2 dimensional (2D) modeling to better characterize flows and velocities in this complex channel area. Likewise, we recommend 2D modeling in the spillway area and mouth of the Falls River to the point where the channel constricts given this complex area with numerous potential flow discharge locations.

The flow study should incorporate the identified minimum flow and temporal parameters for shortnose sturgeon discussed in the Background and Existing Information section of this request.

Level of Effort/Cost, and Why Alternative Studies Will Not Suffice

Field work for flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. Field work associated with this study could be done in conjunction with the below-project instream flow study request. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects (e.g., the Glendale Project, FERC No. 2801).

Requested Study No. 2.
In-stream Flow Habitat Assessment Downstream of Cabot Station

Conduct an instream flow habitat study to assess the impacts of the range of the proposed project discharges on the wetted area and optimal habitat for key species. The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species and benthic invertebrate communities. Target fish species include: state listed (endangered) shortnose sturgeon, American shad, fallfish, and white sucker.

Goals and Objectives

The goal of this study is to determine an appropriate flow regime that will protect and enhance the aquatic resources from the Cabot tailrace of the Turners Falls Project downstream to the Rt. 116 bridge in Sunderland, MA. Specifically, the objective of the study is to conduct an instream flow habitat study to assess the impacts of a range of flows on the wetted area and optimal habitat for key species, including the impacts of hydropeaking flow fluctuations on the quantity and location of aquatic habitat.

The study should include non-steady flow approaches to assess effects of within-day flow fluctuations due to peaking power operations on target fish species and benthic invertebrate communities. Target fish species include: state endangered shortnose sturgeon, American shad, fallfish, white sucker and walleye.

For shortnose sturgeon, the flow study will need to evaluate bottom velocities in shortnose sturgeon spawning and rearing areas during discharge conditions normally observed from April 15th to June 22nd. Protection of shortnose sturgeon spawning will necessitate establishment of discharges that create bottom velocities suitable for shortnose sturgeon spawning and rearing over a sustained period of time and avoid dramatically fluctuating flows. To protect shortnose sturgeon rearing, adequate discharge without dramatic flow fluctuations are needed to ensure the rearing shoals are wetted and velocities are sufficiently protective for early life stage (ELS) rearing.

Field verification will be necessary to confirm the flow modeling results that identify the flows needed to provide sustained bottom velocities for spawning also maintain flows, depths, and water release regime adequate for spawning and rearing. Velocity and depth data should be collected under each potential operation scenarios such that actual velocity, depth, and flow conditions occurring across the entire spawning and rearing areas including wetted shoals.

Resource Management Goals

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to aquatic resources, the Division's goals are:

- Protect, enhance, or restore diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Provide an instream flow regime that meets the life history requirements of resident and migratory fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize current and potential negative project operation effects on water quality and aquatic habitat.
- Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing at the Cabot Station spawning and rearing site.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Presently FirstLight is required to release 1,433 cfs below the Project. Information included in the PAD does not provide a detailed description of how this minimum flow was established and the Division is not aware of any previously conducted studies that evaluated the adequacy of this minimum flow in protecting aquatic resources in the 10+ miles of riverine habitat below the Cabot Station. Therefore, in order to fill this important information gap, an empirical study is needed to provide information on the relationship between flow and habitat in the Connecticut River downstream of the Cabot tailrace. Results will be used by the Division to determine an appropriate flow recommendation.

Kynard et al. (2012, chapter 3) examined the effects of water manipulation at the Turners Falls project on shortnose sturgeon spawning over the course of 17 years. This body of data represents the best available scientific information which does not support 1,433 cfs as an adequate minimum flow to support successful shortnose sturgeon spawning at Cabot Station. Peaking operations at Cabot Station cause discharge fluctuations to rapidly change bottom velocities from 0.4 m/s to 1/3 m/s over 30 minutes (Kynard et al. 2012, chapter 3). Shortnose sturgeon have not evolved to adapt to such artificial rapid changes in velocities and therefore continue to spawn during fluctuations even though conditions may be unsuitable and likely result in high egg mortality. During the 10 years when spawning succeeded at Cabot Station, discharge flow decreased to less than 35,460 cfs by April 29th. The lowest discharge level observed while females remained on the spawning site was 4,700 cfs. Spawning behavior was not monitored during Cabot Station discharges at or below 3,500 cfs, so it is unclear what the minimum flow threshold is for spawning at Cabot Station. When peaking generation discharges cease during naturally low flow years, the tailrace shoals, likely used by shortnose ELS for rearing, were exposed (observed during years '95, '98-99, '04) and may have resulted in larvae mortality due to stranding and exposure (Kynard et al 2012, chapter 3). Researchers observed that shoal exposure began when river flow below Cabot Station dropped below 7,062 cfs (Kieffer and Kynard 2007). Thus, total flow at Cabot, which may include flow from the Turners Falls Dam or Station 1, must be at least 7,062 cfs to both support adequate bottom velocities and prevent shoal exposure.

Furthermore, the emergency water control gates at Cabot Station that are used to sluice trash from the canal and balance canal flows spill large amounts of water. These large spill events create a plume of turbid turbulent flow, which caused some females to leave the area. These spill events scour bottom sediments which are then carried downstream over the spawning and rearing shoals where an entire year class of early life stages may be destroyed (Kynard et al. 2012, chapter 3). Information included in the PAD does not address adequate flows for shortnose sturgeon spawning and rearing. Results of the requested modeling will be used by the Divisions to determine an appropriate flow recommendation.

Researchers have also looked at suitable depth and velocity habitat for spawning (Kieffer and Kynard 1996, Kynard et al. 2012, chapter 3). Spawning sites are characterized by moderate river flows with average bottom velocities between 0.4 and 0.8 m/s (Hall et al. 1991, Kieffer and Kynard 1996, NMFS 1998). Water depth at the spawning site appears to be a less important habitat feature than substrate type and flow. A recent study by Kynard et al. (2012, chapter 6) demonstrated that females in an artificial stream will readily accept a shallow water depth of 0.6 m, with a rubble bottom, and 0.3–1.2 m/s bottom velocity. In addition, although eggs and embryos can likely tolerate very low depths, researchers measuring water depths between Turners Falls Dam and Cabot Station in order to recommend minimum flows suitable for an escape route for shortnose sturgeon trapped in the Turners Falls Dam Plunge Pool used a minimum depth of 1.5 x adult body depth. Because adults spawning in an artificial spawning channel frequently positioned themselves on top of one another (Kynard et al. 2012 Chapter 6), a minimum depth to facilitate spawning within the known Cabot Station spawning area is 3.0 body depths, or 19.2 inches.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Nexus to Project

The Project is currently operated with a minimum flow release that was not based on biological criteria or field study. Further, the project generates power in a peaking mode resulting in significant with-in day flow fluctuations between the minimum and project capacity on hourly or daily basis. The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project (Cushman 1985, Blinn 1995, Freeman *et al.* 2001). There are more than ten miles of lotic habitat below the project's discharge that are impacted by peaking operations at Cabot Station. This section of the Connecticut River contains habitat that supports native riverine species, including important spawning and rearing habitat for migratory fish such as American shad and state endangered shortnose sturgeon. Shortnose sturgeon larval migrants initially become bottom dwellers and transition from living off of yolk sacs to orally feeding, which is a critical stage in their life history. While the existing license does require a continuous flow of 1,433 cfs below the project (0.20 cubic feet per second flow per square mile of drainage area - cfs/m), that is equal to only 40% of the Aquatic Base Flow⁴ this flow does not sufficiently protect the aquatic resources, including endangered species, in this substantial reach of river, especially in the context of the magnitude, frequency, and duration of changes in habitat that likely occur between minimum and generation flows.

Results of the flow study will be used by the Division to determine an appropriate flow recommendation that will protect and/or enhance the aquatic resources below the Project.

Methodology Consistent with Accepted Practice

In-stream flow habitat assessments are commonly employed in developing plant operational regimes that will reduce impacts or enhance habitat conditions downstream of hydroelectric projects.

The Division requests a flow study be conducted at the Project. Given the length of the river reach (10+ miles) impacted by project operations, we believe a study methodology that utilizes an IFIM approach is appropriate for this site. This same protocol was used during the relicensing of the Housatonic River Project (FERC No. 2576),⁵ and has been accepted by the Commission in other licensing proceedings⁶.

At a minimum, the study design should involve collecting wetted perimeter, depth, velocity, and substrate data along transects located in the reach of river below Cabot Station. The measurements should be taken over a range of test flows. This information then should be synthesized to quantify habitat suitability (using mutually agreed upon HSI curves) of each test flow for target species identified by the fisheries agencies. Habitat modeling using standard PHABSIM 1 dimensional modeling is acceptable for the river channel downstream from the railroad bridge below the mouth of the Deerfield River. The area from the Cabot Station discharge to the railroad bridge should be modeled using 2 dimensional (2D) modeling to better characterize flows and velocities in this complex channel area.

The types of data collected with this study should be sufficient to perform a dual-flow analysis and habitat time series or similar approaches that will permit assessment of how quality and location of habitat for target species changes over a range of flows between existing minimum flow and maximum project generation flows.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Field work for instream flow studies can be reasonably extensive but will depend on consultation with the applicant on study methodology and on-site decisions on locations for data collection and the number of collection locations. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

⁴ The Aquatic Base Flow equates to the August Median Flow as determined using unregulated hydrography or on drainage area at the project site (0.5 cfs per square mile of drainage area) if unregulated hydrography is unavailable.

Requested Study No. 3.

Telemetry Study of Upstream and Downstream Migrating Adult American Shad to Assess Passage Routes, Effectiveness, Delays, and Survival

Goals and Objectives

Assess behavior, approach routes, passage success, survival, and delay by adult American shad as they encounter the projects during both upstream and downstream migrations, under permitted project operations conditions, proposed operational conditions, and study treatment operational conditions. There are multiple fishways and issues related to both upstream and downstream passage success at the projects.

Telemetry Study - This requested study requires use of telemetry using both radio and Passive Integrated Transponder (PIT) tag types to provide information to address multiple upstream and downstream fish passage issues. The following objectives shall be addressed in these studies:

- Assessment of any migration delays resulting from the presence of the dam and peaking flow operations of the Turners Falls Project;
- Determine route selection and behavior of upstream migrating shad at the Turners Falls Project under various spill flow levels (e.g., movement to the dam, attraction to Cabot Station, attraction to Station 1 discharge, movement between locations, delay, timing, etc.). A plan and schedule for dam spill flow releases will need to be developed that provides sufficient periods of spill flow conditions, and various generating levels from Turners #1 Station coupled with Cabot Station generation flows (e.g., treatments will require multiple days of consistent discharge). Evaluated spill flows should include flows between 2,500 – 6,300 cfs, which relate to bypass flows identified as providing spawning opportunities for shortnose sturgeon in the lower bypass reach at the Rock Dam. (Kieffer and Kynard 2012). Sturgeon spawning and upstream shad passage occur concurrently;
- Assess near field attraction to, and entrance efficiency of the Spillway Ladder by shad reaching the dam spillway, under a range of spill conditions;
- Evaluate the internal efficiency of the Turners Falls Spillway Ladder;
- Continue data collection of Cabot Station Ladder and Gatehouse Ladder efficiency, to include rates of approach to fishway entrances, entry into fishways, and passage through them, under different operational conditions that occur in these areas;
- Evaluate modifications to the Cabot and/or Spillway fishways recommended by the Division if they are implemented;
- Assess upstream migration from Turners Falls to the Vernon Dam in relation to Northfield Mountain's pumping and generating operations and Vernon Project peaking generation operations. Typical existing and proposed project operation alterations should be evaluated;
- Assess impacts of Northfield Mountain operations on up- and downstream adult shad migration, including delays, entrainment, and behavioral changes and migration direction shifts under existing and proposed project operations;
- Determine downstream passage route selection, timing/delay, and survival under varied project operational flows into the power canal and spill flows at Turners Falls Dam;
- Determine downstream passage route selection, timing/delay in the canal, Cabot Station fish bypass facility effectiveness, and survival of Cabot-bypassed adult shad that enter the Turners Falls Canal system;
- Compare rates and or measures of delay, movement and survival etc., among project areas or routes utilized (e.g., spill at dam vs. power canal) under the range of permitted and proposed conditions; and
- Utilize available data sets and further analyze raw data (e.g., 2003- 2012 Conte Lab Studies) where possible to address these questions and inform power analyses and experimental design.

Information to address all of these questions would rely on the tagging of upstream migrating adult shad at Holyoke Dam and releasing them to migrate naturally from Holyoke through the Turners Falls and Vernon projects and back downstream after spawning. Additional tagged individuals would likely need to be released farther upstream (Turners Falls Canal, upstream of Turners Falls Dam), to ensure that enough tagged individuals encounter project dams on both upstream and downstream migrations, that these individuals are exposed to a sufficient range of turbine and operational conditions to test for project effects, and to provide adequate samples sizes for statistically

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

valid data analyses to address the many objectives listed. This study will require two years of field data collection to attempt to account for inter-annual variability in river discharge and water temperatures.

Evaluation of Past Study Data- In addition to collection and analysis of new telemetry data, substantial data has already been collected at Turners Falls from multiple years of passage assessments conducted for First Light by U.S. Geological Survey's Conte Anadromous Fish Research Center (Conte Lab) researchers and there are also data from the 2011 and 2012 full river study conducted by the Conte Lab that address Turners Falls, Northfield Mountain and Vernon project migration and passage questions that have not yet been analyzed. These data include several million records each year from more than 30 radio telemetry receivers deployed between Middletown, CT and Vernon Dam. This data will provide substantial information free from the field data collection costs and therefore should be analyzed as part of this study. This data analysis should be completed in 2013 to help inform the design of subsequent field studies.

Evaluation of Methods to Get Shad Past Cabot Station for Spillway Passage at the Turners Falls Dam – The poor passage efficiency of the Cabot Ladder, the first and most used fishway encountered by shad arriving at the Turners Falls Project, and at the entrance to the Gatehouse Ladder, which all Cabot fishway-passed fish must use, has resulted in very poor overall shad passage efficiency at the project. An alternative to passing fish at the Cabot Station is to install a fish lift at the dam that would put fish directly into the Turners Falls pool, thereby eliminating problems with the Cabot Fishway, and the Gatehouse Fishway entrance and the variable passage efficiency of the Gatehouse Fishway. For this to be effective, attraction of shad to the Cabot Station discharge and associated delays would need to be overcome. It is possible that spillway flow releases coupled with behavioral measures at Cabot Station that dissuade shad from that tailrace could achieve this end. In order to assess the possibilities, we recommend the following study:

- A literature search and desk-top assessment of the possible behavioral measures that could be effective in getting shad to pass Cabot Station tailrace and continue upstream to the dam.
- Based on results of the desk-top assessment, possible evaluation of behavioral measures that are likely to be effective.
- Field evaluation of the effect of different levels of spill at the dam that would induce fish to move past the Cabot Station into the bypass reach and up to the dam (as noted in objectives).

Besides passage success and delays at passage facilities, these studies would assess the impacts of project operations on migration passage delay, route, timing, injury, mortality, and passage structure attraction, retention, and success. Of particular interest will be fish behavior during periods when flow releases from the project increase from the required minimum flows to peak generation flows and when flows subside from peak generation flows to minimum flows and the operation of NMPS in pumping and generation modes.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
- Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

- Maximize the number of juvenile recruits emigrating from freshwater stock complexes and recommendations:
- Upstream Passage –

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- American shad must be able to locate, enter, and pass the passage facility with little effort and without stress.
- Where appropriate, improve upstream fish passage effectiveness through operational or structural modifications at impediments to migration.
- Fish that have ascended the passage facility should be guided/routed to an appropriate area so that they can continue upstream migration, and avoid being swept back downstream below the obstruction.
- Downstream Passage –
 - To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the least delay and best survival rate.

Based on the CRASC plan, the Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad movement and migration, the Division's goals are:

- Minimize current and potential negative project operation effects such as migration delays, false attraction, turbine entrainment, survival of project passage routes, and trashrack impingement that could hinder management goals and objectives.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a fish and wildlife resource agency.

Background and Existing Information

Passage of adult shad at the Turners Falls fishway complex has been the subject of intense study by the Conte Lab since before 1999. These studies have clearly demonstrated that passage through the existing fishways at Cabot and Spillway is poor (<10% in many years). Passage through the Gatehouse fishway is better, but still rarely exceeds 80%, despite the short length of this ladder. In addition to poor passage for fish entering the ladders, shad that ascend the Cabot Fishway experience extensive delays before entry into the Gatehouse Fishway. Shad that ascend Spillway frequently fall back into the canal and are also subject to these upstream delays. A new entrance to the Gatehouse Fishway installed in 2007 led to dramatic improvements in passage out of the canal (from 5% to over 50% in 2011), but passage still falls well short of management goals. In addition, shad spend considerable time (up to several weeks) attempting to pass. These delays likely influence spawning success and survival. Adult shad, unable to pass Gatehouse, experience similar delays in downstream passage, even after they have stopped trying to pass Gatehouse. Without spill, all outmigrating shad that have passed Gatehouse must enter the canal at the Gatehouse and may be subject to delays exiting the canal.

During the course of these studies a very large dataset has been compiled that could yield useful information for further improving passage of shad out of the canal in both the upstream and downstream directions. A unique feature of these data is a 2-dimensional array covering the canal just downstream of Gatehouse, documenting fine scale movements and occupancy of this zone. These data should be combined with computational fluid dynamics (CFD) and real-time hydraulic data to determine how canal hydraulics influence the ability of shad to locate and enter the fishway, and to identify modifications that are likely to lead to improvements in approach and entry rates. A separate

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

CFD modeling study is requested that includes modeling of the Gatehouse Fishway entrance are at the head of the power canal.

In addition, whole-river shad telemetry studies performed in 2011 and 2012 will likely provide useful information and should be analyzed. These data should allow quantification of delay below Turners Falls, and could help guide studies requested above. Preliminary analyses of data through 2011 have been made available to FirstLight and the resource agencies (Castro-Santos and Haro 2005; Castro-Santos and Haro 2010).

The whole-river studies have also shown that, at least in 2011, most shad that pass Turners Falls rapidly progress upstream to Vernon Dam where extensive delays also occur. Data from the 2012 study were not available at this time, but Dr. Castro-Santos stated similar patterns were noted in the data between the years on the topic of upstream delay (personal communication, Dr. Theodore Castro-Santos). Similarly, concerns relative to the downstream passage of spent shad also remain relative to delays, with existing unpublished USGS telemetry data sets suggesting this is an issue within the Turners Falls canal.

Since the first year of operation of the Turners Falls upstream fishways (1980), the percent passage of American shad annually passed upstream of Turners Falls Dam compared to the number passed at the Holyoke Fish Lift has averaged 3.6% (1980-2012 data). The highest values for this metric has not exceed 11% and are well below the noted CRASC Management Plan target range for this objective noted earlier as 40-60% on a five year running average.

Since the first year of operation of the Vernon Dam upstream fish ladder (1981), the percent passage of American shad annually passed at Vernon compared to the number passed upstream of Turners Falls Dam (Gatehouse counts) has averaged 39.4%, ranging from 0.42% to 116.4% (> 100% due to counting error at one or both facilities, unknown).

Nexus to Project

Existing project operations (peaking power generation) and limited bypass flows have a direct impact on instream flow and zones of passage (migration corridors). Project flow releases affect passage route selection, entry into fishways, and create delays to upstream migration. Inefficient downstream bypasses can result in migration delays and increased turbine passage. Mortality of adult shad passing through these turbines is expected to be high (Bell and Kynard 1985), additional stresses associated with passage and delay may cause mortality as shad are unable to return to salt water in a timely manner. The project's upstream and downstream passage facilities need to be designed and operated to provide timely and effective upstream and downstream fish passage to meet restoration goals of passage to upstream habitat and maximize post-spawn survival. These factors are all critically important to the success of restoration efforts.

Methodology Consistent with Accepted Practice

Use of radio including passive-integrated transponder (PIT) telemetry is widely accepted as the best method to assess fish migratory behavior and passage success and has been used extensively to assess migration and passage issues at Turners Falls as well as other Connecticut River projects. These studies include one conducted in 2011 and 2012 by the U.S. Fish and Wildlife Service and U.S. Geological Survey's Conte Anadromous Fish Research Center, which has provided substantial information related to some of the issues identified here. The requested study will build and expand on the information collected over the past two years.

The study design must specify sample sizes, tag configurations and receiver configurations, to ensure that rates of entry and exit to the tailraces, fishways, downstream bypasses, and the bypassed reach can be calculated with sufficient precision to determine effectiveness of flow. For project assessments at Turners Falls (e.g., Cabot, Spillway and Gatehouse ladder attraction and entry, route selection, operational effects), double tagged (radio and PIT) shad will be required for release from Holyoke Dam. Additional shad must be released directly into the Turners Falls Canal to support assessment of the various operational and structural conditions in effect, to be modified in this period, and proposed conditions within the Turners Falls power canal relative to entrances to the Gatehouse fishway. A related request on CFD modeling in the Cabot Station tailrace, the upper power canal near Gatehouse, and in the area around the entrance of the Spillway Ladder will address related project operational

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

effects that will also address identified objectives in this telemetry request. Shad captured at Holyoke and tagged and release upstream of Turners Falls Dam, or tagged out of Gatehouse Ladder, would help to ensure an adequate sample size for evaluations in the vicinity of NMPS and to the Vernon Dam and the ability to address identified study objectives in those project areas. Additional tagged shad are expected to be required for release upstream of the Vernon Dam, which should ensure adequate sample for a separate study request, where shad spawn upstream of Vernon Dam as well as ensuring there is an adequate number of outmigrating spent adults to address related study objectives for adult outmigrants. The required number of tagged fish to address study objectives may be adjusted accordingly from area to area depending on target numbers (i.e., best information on resultant viable tagged fish and power analyses to detect effects) to account for typical passage rates, survival rates, and handling effects as examples.

Existing information on captured, handled, tagged fish performance (e.g., percent that drop back, unsuitable for tracking) and factors such as timing of tagging and potentially transport, must all be carefully considered to ensure an adequate sample size of healthy (e.g., viable to characterize behavior, survival, etc.) tagged fish is available to address the many questions identified in this request (as supported by a statistical power analysis). Additionally, ensuring adequate downstream adult fish sample sizes (to address project effect questions above) requires close consideration as expected losses of healthy tagged fish during upstream passage, natural mortality rates, and tagging related effects, are expected to reduce sample sizes on downstream passage objectives/questions as the season progresses. The use of single PIT tagged fish can help improve sample sizes, but will be of limited use to answer some of the passage questions we have identified.

Due to environmental variability, two years of study work will be necessary. A large array of stationary monitoring stations (radio and PIT) will be needed to address the issues identified among the project areas. A sufficient level of radio receiver and PIT reader coverage will be required, to provide an appropriate level of resolution, for data analyses, to answer these questions on project operational effects. The study will provide information on a variety of structural and operational aspects of fish migration, relative to route selection, timing, survival, and up and downstream passage attraction, retention, delay, efficiency, survival as some examples at three projects (Turners Falls, NMPS, and Vernon). The use of video monitoring may also be utilized for specific study areas such as the Spillway Ladder, to provide additional information on shad entrance activity, with the understanding of some data limitations associated with this approach (fish identification, water visibility).

In addition to the tagging studies, use of video monitoring of the Spillway Fishway would provide additional overall data on Spillway Fishway efficiency as all shad attempting to pass could be monitored versus just those shad that have been tagged.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The requested study is extensive and will require a substantial effort and cost to capture, PIT tag, and radio tag a sufficient number of shad at Holyoke to release at upstream locations. We are not aware of any other study technique that would provide project specific fish behavior and migration information to adequately assess existing project operations and provide insight in possible alternative operations and measures needed to address observed negative impacts to fish migration success. Cost for the entire multi-project tagging, tracking and data analysis are expected to range from \$400,000 to \$500,000 based on past Turners Falls' studies and the 2011 and 2012 shad telemetry studies. Video monitoring of the Spillway fishway would add a modest cost to this study.

Due to the fact tagged shad will move throughout the larger five project area, to varying degrees, there will be expected cost savings (e.g., radio tags) to both owner/operators, provided cooperation in study planning and implementation occurs.

Requested Study No. 4.

Impact of Project Operations on Shad Spawning, Spawning Habitat, and Egg Deposition in the Project Area.

Conduct a field study of spawning by American shad in the Connecticut River mainstem downstream of Turners Falls Dam and in the Turners Falls Dam impoundment to determine if project operations (including operations of the Northfield Mountain Pump Storage) negatively impact shad spawning behavior, spawning habitat use, areal extent and quality of those spawning areas, and spawning activity in terms of egg deposition in those areas.

Goals and Objectives

Determine if project operations (under the permitted and proposed operational ranges) affect American shad spawning site use and availability, spawning habitat quantity and quality, and spawning activity in the river reaches downstream from Cabot Station and in the project bypass reach of Turners Falls Dam and in the Turners Falls Dam impoundment and in relation to Northfield Mountain Pump Storage operations. The following objectives will address this request:

- Determine areas utilized by American shad for spawning by conducting night-time visual observation of spawning activity, identify and define areas geospatially, and obtain data on physical habitat conditions effected by project operations (e.g., water depth, velocity, discharge, substrate, exposure and inundation of habitats);
- Determine project operation effects on observed spawning activity, under a range of permitted or proposed project operation conditions;
- Quantify effects (e.g., water velocity, depths, inundation, exposure of habitats) of project operation on identified spawning areas for a range of conditions, over the complete period of spawning activity;
- Quantify spawning activity as measured by night-time spawning/splash surveys and egg collection in areas of spawning activity, and downstream of these areas, to further determine project operation effects (location extent of exposure from changing water levels and flows and on associated habitats from project operations).

If it is determined that the Project operations are adversely affecting the spawning activity of American shad and impacting spawning area habitat, identify operational regimes that will reduce and minimize impacts spawning habitat and spawning success, within the project area. This study will require two years of field data to capture inter-annual variability to river discharge and water temperatures and to allow for evaluation of alternative flow regimes if year one studies determine that the present peaking regime negatively affects spawning.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40% to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.

The Atlantic States Marine Fisheries Commission, Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010 includes the following objective:

- Maximize the number of juvenile recruits emigrating from freshwater stock complexes

and recommendations:

- To mitigate hydrological changes from dams, consider operational changes such as turbine venting, aerating reservoirs upstream of hydroelectric plants, aerating flows downstream, and adjusting in-stream flows.
- Natural river discharge should be taken into account when instream flow alterations are being made to a river (flow regulation) because river flow plays an important role in the migration of diadromous fish.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Ensure that decisions on river flow allocation (e.g., irrigation, evaporative loss, out of basin water transport, hydroelectric operations) take into account instream flow needs for American shad migration, spawning, and nursery use, and minimize deviation from natural flow regimes.
- When considering options for restoring alosine habitat, include study of impacts and possible alteration of dam-related operations to enhance river habitat.

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Division's goals are:

- Minimize current and potential negative project operation effects on American shad spawning and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream from Holyoke Dam. A number of improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad population, and numbers of shad passing Turners Falls and Vernon Dam have not met CRASC management plan objectives. Population number and passage numbers past Holyoke have declined substantially from those totals in recent years, with average Holyoke passage numbers over the last 10 years of 211,850. Since historically approximately half of the returning population of shad to the river passed upstream of Holyoke, recent returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management goals for the Connecticut River.

American shad broadcast spawn in congregations over shallow flats and rocky or sandy substrates (Davis et al, 1970, Mansueti and Kolb 1953), at depths less than 10 feet and often far shallower with spawning fish swimming vigorously near the surface in a closely packed circle (Marcy 1972, Mackenzie et al 1985). Fertilized eggs drift downstream until hatching (Mackenzie et al 1985).

American shad are known to spawn downstream from the Turners Falls Project. Layzer (1974) identified 6 spawning sites from an area below the mouth of the Deerfield River (river mile 191.9) to river mile 161.7 below the Mill River in Hatfield, MA. Kuzmeskus (1977) verified 16 different spawning sites ranging from downstream of the Cabot tailrace to just upstream of the Holyoke dam (river mile 87.1). The only parameter that all spawning sites had in common was current (Kuzmeskus 1977). The Division is not aware of any more recent studies that document whether these 16 sites are still viable spawning locations for shad.

First Light Power conducted studies in the late spring and summer of 2012, examined habitat conditions downstream of the Turners Falls Dam. The study documented that in low flow conditions, Cabot Station project operations produced fluctuations in water level elevations that can range over 4 feet in magnitude (daily operation) at the USGS Montague Gage Station, to lower values of 2 to 3 feet at the Route 116 Bridge, Sunderland, MA (PAD). Similar

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

short-term, limited monitoring in the upper Turners Falls Dam impoundment identified water level changes due to project operations that cyclically varied several feet on a sub-daily frequency.

Nexus to Project

American shad are known to spawn at five locations downstream from the Turners Falls Project from an area below the mouth of the Deerfield River (river mile 191.9) and ten other locations downstream to river mile 161.7 below the Mill River in Hatfield (Layzer 1974, Kuzmeskus 1977).

Shad spawning is likely influenced by river flow, which fluctuates greatly due to the project's peaking mode of operation. These fluctuations may impact shad spawning activity by altering current velocities and water depth at the spawning sites. Effects on spawning behavior could include suspension of spawning activity, poor fertilization, flushing of eggs into unsuitable habitat due to higher peaking discharges, eggs dropping out into unsuitable substrate and being covered by sediment deposition and/or eggs becoming stranded on dewatered shoal areas as peak flows subside.

While a number of shad spawning and egg deposition studies were conducted in the 1970s, that research was aimed at assessing the potential impact of developing a nuclear power station in the Montague Plains section of the Connecticut River. The Division is not aware of any studies being conducted specifically designed to determine if a relationship between spawning behavior, habitat use, and egg deposition and project operations effects of the Turners Falls, Northfield Mountain Pump Storage.

The Division is concerned that peaking operations may be altering spawning behavior and contributing to the failure of the Connecticut River shad population to meet management targets.

Methodology Consistent with Accepted Practice

The first year of study should examine known spawning areas downstream of the Turners Falls Dam project, to determine operation effects on shad spawning behavior, activity, and success. In areas upstream of Turners Falls Dam to the Bellow Falls Dam tailrace, the study should identify areas utilized for spawning by American shad. In the second year, should results from year one determine project operations affected spawning activity, access to habitat, or success, downstream of Turners Falls Dam, then an identical more detailed assessment (identified objectives) should be conducted in spawning areas upstream of Turners Falls Dam to the Bellows Falls Dam tailwater. Measures to reduce or eliminate any documented project operation impacts should be explored and evaluated in year two, downstream of Turners Falls Dam.

The impacts to spawning behavior would best be studied by night-time observations of actual in-river spawning behavior (Ross et al. 1993). Project discharge increases or decreases during actual observed spawning activity will provide empirical evidence of change in behaviors. The observational methodology should follow the protocol specified in Layzer (1974) and/or as described in Ross et al. (1993). The analysis should utilize the observational field data in conjunction with operational data from the projects (station generation and spill on a sub-hourly basis). To assess the impacts of changes in generation flows, the study should include scheduled changes in project operation to ensure that routine generation changes that occur during the nighttime spawning period affect downstream spawning habitats selected for study while shad are spawning. Stier and Crance (1985) provide optimal water velocities during spawning to range between 1 to 3 ft/sec.

In areas used for spawning, the characteristics of those areas (e.g., location, depth, flow, substrate) should be recorded. The effect of project operations (discharge, water velocity, inundation and exposure) should be assessed. Drift nets will be used to collect eggs to quantify egg production before and after flow changes at the spawning site.

In the reaches above the Turners Falls dam, night time observations of splashing associated with shad spawning should be done in each reach as sufficient numbers of shad are passed above each dam. Observations should be done regularly until the end of the spawning season. The use of radio-tagged adult shad from a separate Study Request will aid in this effort. An estimate of the total area used for spawning and an index of spawning activity should be recorded for each site.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Level of Effort/Cost, and Why Alternative Studies will not suffice

First Light has not proposed any studies to meet this need. Estimated cost for the study is expected to be moderate (up to \$40,000), with the majority of costs associated with fieldwork labor.

Requested Study No. 5.
Shad Population Model for the Connecticut River

Develop an American shad annual step, mathematical simulation population model for the Connecticut River to quantify how project operations and potential restoration/mitigation measures impact the population of shad in the Connecticut River.

Goals and Objectives

The goal of the model is to assess impacts of both upstream and downstream passage at each of the Connecticut River projects and potential management options for increasing returns to the river.

Specific objectives include:

- Annual projections of returns to the Connecticut River;
- A deterministic and stochastic option for model runs
- Life history inputs of Connecticut River shad
- Understanding the effect of upstream and downstream passage delay at projects
- Calibration of the model with existing data
- Analysis of the sensitivity of model inputs
- Analysis of sensitivity to different levels of up- and downstream passage efficiencies at all projects
- Multiple output formats including a spreadsheet with yearly outputs for each input and output parameter

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
- Maximize outmigrant survival for juvenile and spent adult shad.

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Division's goals are:

- Minimize current and potential negative project operation effects on American shad spawning and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the first fish lift facility at Holyoke Dam in 1967, American shad have had access to spawning and rearing habitat upstream from Holyoke Dam. A number of improvements to the Holyoke fishway have occurred since that time, but while the numbers of shad lifted at Holyoke have reached as much as 721,764 and

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

the overall shad population to the river exceeded 1.6 million shad in 1992 (CRASC 1992), total shad populations, and numbers of shad passing Holyoke, Turners Falls and Vernon Dam have not met CRASC management goals.

Population and passage numbers past Holyoke have declined substantially from those totals in recent years, with average Holyoke passage numbers since 2000 of 229,876. Whole river population estimates have shown that approximately half of the returning population of shad pass upstream of Holyoke. Recent returns to Holyoke are far below management goals. Average passage efficiency of shad at Turners Falls (Gatehouse counts) and Vernon since 2000 has been 3.1 and 20.4 % respectively. These too are well below the CRASC management goals.

Safe, timely and effective up- and downstream passage along with successful spawning and juvenile production are necessary to help achieve shad management goals for the Connecticut River.

Nexus to Project

Existing project operations and fish ladder efficiencies have a direct effect on shad populations in the Connecticut River. Poor upstream passage efficiencies and delays restrict river access to returning shad. Fish unable to reach upriver spawning grounds may not spawn or have reduced fitness or survival of young. Poor downstream passage survival and downstream passage delays affect outmigration and consequently repeat spawning, an important ecological aspect of the iteroparous Connecticut River shad population (Limberg et al. 2003).

The Division is concerned that poor passage efficiencies and delays at projects may be limiting access to upstream reaches of the river, altering spawning behavior, decreasing outmigration survival and contributing to the failure of the Connecticut River shad population to meet management targets (Castro-Santos and Letcher 2010).

Development of a population model will allow an assessment of individual project impacts on the population as well as the cumulative impacts of multiple projects. The model will allow managers to direct their efforts in the most efficient manner toward remedying the conditions that most impact the shad population.

Methodology Consistent with Accepted Practice

Population models are commonly used to assess anthropomorphic and natural impacts and are consistent with accepted practice. A model similar to this request was constructed for the Susquehanna River by Exelon (FERC #405, RSP 3.4). The model is constructed in Microsoft Access

Specific parameters that would be included in the model:

- Upstream passage efficiency at Holyoke, Turners Falls (Cabot, Gatehouse and Spillway Ladders), Vernon fishways, and any impacts associated with Northfield Mountain.
- Distribution of shad approaching the Turners Falls project between the Cabot Ladder and the spillway at the dam
- Downstream passage efficiencies at Vernon, Northfield Mountain, Turners Falls, and Holyoke projects for juveniles and adults
- Entrainment at Mount Tom and Vermont Yankee
- Sex ratio of returning adults
- The proportion of virgin female adults returning at 4, 5, 6, and 7 years
- The proportion of repeat spawning females at 5, 6 and 7 years
- Spawning success of females in each reach
- Fecundity
- Percent egg deposition
- Fertilization success
- Larval and juvenile in-river survival
- Calibration factor to account for unknown parameters such as at sea survival
- Options for fry stocking and trucking as enhancement measures
- Start year and model run years
- Start population
- Rates of movement to and between barriers

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Temperature, river discharge, and other variable of influence to migration and other life history events

The model should be adaptable to allow the input of new data and other inputs.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Neither First Light nor TransCanada have proposed any study to meet this need. Estimated cost for the study is expected to be low to moderate. As the model describes the impacts of multiple projects and two owners, both project owners would share the cost of model development.

Requested Study No. 6.

Impact of Project Operations on Downstream Migration of Juvenile American Shad

Conduct a field study of juvenile American shad outmigration in the Turners Falls impoundment and the power canal and at Turners Falls Dam, Station #1, and Cabot Station to determine if project operations negatively impact juvenile American shad survival and production.

Goals and Objectives

Determine if project operations affect juvenile American shad outmigration survival, recruitment, and production. The following objectives will address this request:

- Assess project operations effects of NMPS and Turners Falls Dam on the timing, orientation, routes, migration rates, and survival of juvenile shad;
- Determine the proportion of juvenile shad that select the Gatehouse into the power canal versus the dam spill gates as a downstream passage route, under varied operational conditions, including a range of spill conditions up to full spill;
- Determine if there are any delays with downstream movement related to either spill via dam gates or through the Gatehouse and within the impoundment due to operations (i.e., NMPS pumping and generation);
- Determine survival rates for juvenile spilled over/through dam gates, under varied operation conditions, including up to full spill during the annual fall power canal outage period;
- Determine the juvenile downstream passage timing and route selection in the power canal to: Station 1; Cabot Station; and the Cabot Station log sluice bypass, and assess delays associated with each of these locations and with project operations (e.g., stockpiling in the canal);
- Based upon year 1 study results on route selection, determine the survival rate for juvenile shad entrained into Station 1; and
- Determine the survival rates for juvenile shad entrained into Cabot Station units;

If it is determined that the Project operations are adversely affecting juvenile shad survival, migration timing, or other deleterious population effects, identify operational solutions or other passage measures that will reduce and minimize these impacts within the project area. This study will require two years of field data to capture inter-annual variability of river discharge, water temperatures, and variability in the timing and abundance of juvenile production and their outmigration timing, which may relate to spring, summer, and fall conditions. This study will compliment the NMPS Fish Entrainment Study Request which includes assessment of impacts to juvenile shad.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Maximize outmigrant survival for juvenile and spent adult shad.
-

The Atlantic States Marine Fisheries Commission *Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management)*, approved in 2010 includes the following objective:

- Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

and Recommendation:

- To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to American shad, the Division's goals are:

- Minimize current and potential negative project operation effects on juvenile American shad survival, production, and recruitment.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Since the construction of the Turners Falls Dam upstream fishways in 1980, American shad have had access to spawning and rearing habitat upstream of Turners Dam. A number of modifications to the Turners Falls fishways have occurred since that time, with the numbers of adult shad passed at Gatehouse Ladder (into Turners Falls Dam impoundment) reaching as much 60,089 in 1992 when a record 721,764 shad passed upstream of Holyoke Dam. However, since 1980 an average of only 3.6 % of the adult shad passed upstream of Holyoke Dam subsequently have passed upstream of Turners Falls Dam, and this value has never exceeded 11%. This value is well below the CRASC 1992 Shad Plan objective of 40-60% passage from the previous dam. In addition, population number and passage numbers past Holyoke have declined substantially, with the average Holyoke passage number over the last 10 years being 211,850. Because historic data suggests that approximately half the returning adult shad to the Connecticut River pass the Holyoke Dam, recent adult returns are far below management goals. Effective upstream and downstream passage and successful in-river spawning and juvenile production are necessary to help achieve shad management restoration goals for the Connecticut River, which extends to the Bellows Falls Dam. In 1990, FirstLight's predecessor, Northeast Utilities, CRASC and its member agencies, signed an MOA on downstream fish passage to address both juvenile and adults at the Turners Falls Project and Northfield Mountain Pumped Storage Project.

American shad broadcast spawn with the highest spawning activity occurring in runs and lowest activity in pools and riffle/pools (Ross et al. 1993). Field research by Ross et al. (1993) in the Delaware River further noted that a combination of physical characteristics that seems to be avoided by spawning adults is slow current and greater depth. American shad year-class strength has been shown to depend on parent stock size and environmental conditions during the larval life stages (Crecco and Savoy 1984). Delays in juvenile American shad outmigration may affect survival rates in the transition to the marine environment (Zydlewski et al. 2003). One published study on the Connecticut River, identified that juvenile shad outmigration began when declining autumn temperatures reached 19C and peaked at 16C (O'Leary and Kynard 1986).

Juvenile American shad production has been monitored upstream of the Vernon Dam and immediately downstream of that dam by Vermont Yankee Nuclear as part of an annual monitoring program using both boat electrofishing (since 1991) and beach seining (since 2000). Sampling of juvenile shad was also conducted by a contractor hired by Northeast Utilities in the Turners Falls impoundment in 1992. O'Donnell and Letcher (2008) examined juvenile shad early life history and migration upstream and downstream of Turners Falls Dam. Their study results led to the decision by the agencies to require earlier operation of downstream fishways to protect early season juvenile shad out-migrants (1 September prior to 2010, 15 August in 2010, and since 2011, 1 August).

Downstream juvenile clupeid passage studies at Turners Falls were conducted in the fall of 1991 which included the objectives of determining the percentage of juvenile shad and herring that pass via the bypass log sluice or that were entrained in the Cabot Station turbines and related data (e.g., catch rates) were compared. The 1991 Downstream Clupeid Study did not assess survival rates for juveniles for either of these passage routes. The 1991 study report documented a higher rate of entrainment into the project turbines (23.0 fish per minute) versus through the bypass

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

sluice (11.6 fish per minute). It was concluded that only an estimated 54% (average bypass rate, weighted by estimated number bypassed) of the juvenile American shad approaching Cabot Station were bypassed via the log sluice. The range of the percent bypassed varied widely by date, between nearly 0 and 83%, with “no clear explanation as to why.” The report did not identify the percentage entrained into the turbines but it can be reasoned to be substantial based on the data presented in the report or assumed as the remaining balance (46%) as there were no spill events reported during this study, and therefore nowhere else for them to pass. It was further noted that entrainment rates for juveniles were consistently greatest for units 1 and 6 (ends), not uniform across all units. Although no concurrent bypass sampling occurred during the first entrainment sampling events, it was noted that “entrainment rates were relatively high during the end of September.” Additional modifications have occurred over time without quantitative evaluation to improve downstream passage attraction and use to the bypass sluice, including lighting systems.

The 1994 Downstream Juvenile Shad Study report assessed juvenile shad survival from passage via the log sluice, reported to be 98%, based on tagged and recaptured fish (held for up to 48 hours). Scale loss (<20%) (22 of treatment fish) compared with scale loss of >20% (5 of treatment fish) was examined and determined to occur in an overall total of 10% of study fish (adjusted by control fish data).

Nexus to Project

Adult American shad passed upstream of Turners Falls Dam utilize upstream spawning habitat. Juvenile American shad production occurs in these habitats upstream of Turners Falls Dam on an annual basis. Juvenile American shad require safe and timely downstream passage measures to have the opportunity to contribute to the fishery agencies’ target restoration population size.

The Division is not aware of any studies being conducted specifically designed to determine:

- When spill gates are open at the Turners Falls Dam?;
- What proportion of juvenile outmigrant shad take that route of passage?;
- What is the rate of survival under a range of spill and gate configurations?
- What is the timing, duration, and magnitude of juvenile shad outmigrants in summer and fall to the Turners Falls Dam and Gatehouse?
- Are there delays in migration/movement at the dam, Gatehouse, Cabot Station, or Station 1?
- For juveniles that enter the power canal, what proportion subsequently enter the Station 1 power canal?
- As there is no downstream passage facilities at Station #1, and trash rack spacing is 2.6 inches, what is the survival rate of juvenile shad entrained at Station #1?
- What is the rate of movement through the Turners Power Canal, relative to r delay to outmigrant juvenile shad and the potential accumulation of juveniles (e.g., prior to the canal drawdown in September)?
- What proportion of juvenile shad use the downstream sluice bypass versus the Cabot Station turbines under varied operational conditions given that project operations may change (PAD notes possible increase in turbine capacity at Cabot)?
- Based upon earlier facility studies (1991 Downstream Clupeid) a large proportion and number of juvenile shad are entrained into Cabot Station turbines. What are the associated impacts in terms of short-term and longer term survival and injury (i.e., scale loss)?

The Division is concerned that project operations may impact juvenile shad outmigration survival and be contributing to the failure of the Connecticut River shad population to meet management targets. In the PAD, proposed modification include; Station 1 may be upgraded with new turbines, Station 1 may be closed, and/or the turbine capacity at Cabot may be increased. It is unclear how these scenarios will affect the questions identified in this request.

Methodology Consistent with Accepted Practice

The impact to juvenile shad outmigrants by project operations would be best studied by a combination of approaches including hydroacoustic, radio telemetry, and turbine balloon tags. Project discharge over a full range of existing and, to the extent possible, potential future operational conditions at Station 1 and Cabot, at the dam (likely increased bypass reach flows in new license) and in relation to the Gatehouse, should be examined relative to timing, duration, and magnitude of juvenile shad migration to and through these areas, with hydroacoustic

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

equipment for natural/wild fish evaluation. In addition, study fish should be collected and tagged (PIT, radio, other mark, and balloon) to also empirically determine rates of survival for fish passed over or through the dam's gates, under varied operations, including up to full spill condition that occurs annually in fall with canal outage period. The understanding of the timing, magnitude, duration of the wild fish outmigration will help inform the design, data/results, and assessment of tagged study fish. The release of tagged or marked fish (radio, PIT) upstream of the Gatehouse induction into the power canal, will provide data on concerns of delay and route selection to Station 1, Cabot Station downstream bypass, Cabot Station spill gates, and Cabot Station turbines. Additional hydroacoustic assessment at Cabot Station forebay will provide information on wild/natural juvenile fish timing, magnitude, and duration to and through this area. Based upon Year 1 study findings relative to the frequency, magnitude, timing of juvenile American shad that end up in the forebay of Station 1, the determination of whether an entrainment survival study at that site is necessary will be made. Release sites for tagged fish will be determined based upon further consultation among the parties.

Radio tagged juvenile shad will be released in areas upstream of the NMPS facility at multiple release locations, to determine operation effects on migration rates, route, orientation, entrainment, and survival, over a full range of permitted and operational conditions.

Level of Effort/Cost, and Why Alternative Studies will not suffice

First Light does not propose any studies to meet this need. Estimated cost for the study is expected to be high, between \$200,000 and \$300,000, with the majority of costs associated with equipment (hydroacoustic gear, radio tags, radio receivers, and PIT readers) and related fieldwork labor.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

**Requested Study No. 7.
Upstream American Eel Passage Assessment at Turners Falls**

Goals and Objectives

This study has two objectives:

- Conduct systematic surveys of eel presence/abundance at Cabot Station discharge, Station #1 discharge, canal discharges, and Turners Falls Dam to identify areas of concentration of eels staging in pools or attempting to ascend wetted structures that would potentially establish the most effective locations to place upstream eel passage facilities.
- Collect eels with temporary trap/pass devices from areas identified from surveys as potential locations of eel concentration to assess whether eels can be collected/passed in substantial numbers, and whether locations are viable sites for permanent eel trap/pass structures.

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

- Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
- Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Eel (Anguilla rostrata) in the Connecticut River Basin* in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

- Protect and enhance eel populations where they currently exist;
- Where practical, restore populations to waters where they had historical abundance;
- Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
- Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to upstream passage of American eel, the Division’s goals are:

- Minimize current and potential negative project operation effects that could hinder management goals and objectives.
- Minimize project-related sources of upstream passage delay, injury, and stress in order to facilitate access to historical rearing habitat.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requester is a resource agency.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Existing Information

The PAD contains no information relative to areas where eels seeking to move upstream concentrate downstream of the dam, or annual numbers of eels attempting to ascend past Turners Falls Dam. While eels have been known to ascend the Cabot Station ladder (A. Haro, U.S. Geological Survey, pers. comm.), its efficiency is unknown, and it is only operated during the American shad passage season (from April 1 through July 15). Eels are currently able to pass the Turners Falls Dam complex (as evidenced by documented presence of eels upstream), but the total number of eels attempting to pass Turners Falls and the proportion successfully passing the project is unknown (but suspected to be low). The downstream Holyoke Project has operated upstream eel passage facilities since 2004. Last year these facilities passed over 40,000 juvenile eels. While there is rearing habitat in between the Holyoke and Turners Falls dams, some eels will attempt to continue upstream, and passage needs to be provided so these fish can access historical habitat.

These information gaps need to be filled so resource agencies can determine the best locations to site upstream eel passage facilities and assess whether operating the existing anadromous ladders would be an effective mechanism to move juvenile eels upstream past the project.

We also note that within the past seven years, the U.S. Fish and Wildlife Service (Service) has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability (CESAR). On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made before any new licenses are issued for the projects.

Nexus to Project

The project generates hydropower on the head created by the Turners Falls dam. This dam creates a barrier to upstream migrating eels. While some eels are able to pass dams, some are not, and the passability of a given dam depends on factors such as its height, hydraulics, presence of climbable surfaces, presence of predators, risk of exposure to heat or drying while climbing a dam, etc. The Turners Falls dam is high (35 feet above bedrock), and the majority of the dam face is dry during most of the upstream eel passage season. Design of the dam is not currently amenable to passage of eels by climbing. While flow is released to the bypass reach via a bascule gate (typically the one closest to the gatehouse), this would not facilitate eel passage, as bascule gates open outward and downward (i.e., requiring the eels to essentially swim nearly upside down to get over the gate). As mentioned earlier, the existing anadromous passage facilities are not designed to pass eels, and even if some eels are able to ascend the ladders, they may incur delays (in attraction or passage rates), be size-selective (e.g. velocity barrier for small eels presented by ~8 ft/sec flow through weirs and orifices), present a potential predation risk (predators in or near the fishways), and are not operated throughout the upstream eel passage season.

Methodology Consistent with Accepted Practice

- **Objective 1: Systematic Surveys**
Surveys of eel presence and relative abundance should be conducted at regular intervals throughout the eel upstream migratory season (~1 May to ~15 October, or when river temperatures exceed 10 C). Surveys should consist of visual inspection and trapping in likely areas where eels may concentrate as they attempt to climb structures wetted by significant spill or leakage flow in the Turners Falls dam complex area. These locations include: Cabot Station downstream bypass outfall, Cabot Station spillway (including attraction water stilling basin), Cabot Fishway (dewatered state), USGS Conte Lab flume outfall, Number One Station outfall, various small turbine and process water outfalls from the Cabot Canal, Spillway Fishway attraction water stilling basin, and leakage points along the downstream face of Turners Falls Dam (bascule and taintor gates). Methods should include visual surveys (on foot, from a boat, or snorkeling) and trapping using small mesh (< 1/8" clear opening) baited eel pots. Visual surveys should be performed

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

once per week, at night, preferentially during precipitation events. Trap sets should be performed once per week, with an overnight soak time. Recorded data should include location, observation of eels (presence, absence, relative numbers, relative sizes, behaviors, time/date of observation), and survey method.

- **Objective 2: Trap/Pass Collections**

Areas identified from Systematic Surveys as having significant number of eels present should be targeted as potential areas for permanent eel trap/passes, and should be initially assessed using temporary/portable trap passes. At a minimum (regardless of survey results), temporary trap passes should be installed at the following locations: Cabot Fishway attraction flow stilling basin (during dewatered fishway period), Number One Station outfall, and Spillway Fishway attraction flow stilling basin (during watered and dewatered fishway period), as these locations may be supplemented with additional attraction flow and have high potential for being concentration points for upstream migrant eels. Temporary trap/passes should be purpose-designed and built for each location, and operated throughout the eel upstream migratory season (~1May to 15 October, or when river temperatures exceed 10 C). Ramp-type traps with supplementary attraction flow are preferred temporary trap/pass designs. Traps should operate daily, with catches quantified every 2-3 days. Recorded data should include location, trapping interval, absolute numbers of eels trapped, relative eel sizes, and hydraulic and environmental conditions during the trapping period.

All collected eels from surveys should be released at their point of capture; those eels collected from trap/pass collections should be transported to and released above the dam in the Turners Falls Pool.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the survey component of the study would be low; a minimal number of personnel may be able to conduct the weekly surveys. The trap/pass component would require low to moderate cost (estimated at \$40,000) and effort.

In the PAD, the applicant has identified the need to assess issues related to upstream passage for American eels at the project, but indicates that it intends to rely on information from previously conducted studies and ongoing studies. The Division is not aware of any previously conducted or ongoing studies related to upstream eel passage.

Requested Study No. 8.
Downstream American Eel Passage Assessment at Turners Falls and Northfield Mountain

Goals and Objectives

The goal of this study is to determine the impact of two hydroelectric projects on the outmigration of silver eels in the Connecticut River. Entrainment of eels at the Northfield Mountain Pumped Storage Station (NFMPS) removes eels from the river, effectively removing them from the population. Entrainment into the turbines at Station 1 and Cabot Station of the Turners Falls Project may result in mortality or injury. It is important to understand the passage routes at each project and the potential for mortality to assess alternative management options to increase survival.

The objectives of this study are:

- Quantify the movement rates (including delays) and relative proportion of eels passing via various routes at the projects; i.e. for NFMPS, the proportion entrained into the intake; for Turners Falls Dam, the proportion entrained into the power canal and spilled via bascule and taintor gates; for the Cabot Canal, proportion of fish passing via spillways, turbines, and the downstream bypass.
- Evaluate instantaneous and latent mortality and injury of eels passed via the Turners Falls Dam routes, including bascule and taintor gates, spillways, turbines, and the downstream bypass.

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

- Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
- Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Eel (Anguilla rostrata) in the Connecticut River Basin* in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

- Protect and enhance eel populations where they currently exist;
- Where practical, restore populations to waters where they had historical abundance;
- Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
- Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to downstream passage of American eel, the Division’s goals are:

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Minimize current and potential negative project operation effects that could hinder management goals and objectives.
- Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

The PAD contains information on the biology, life history, and regulatory status of American eel. It also discusses 2-D and 3-D telemetry studies that were conducted at Cabot Station in 1996, 1997, 2002 and 2003. Results of those studies indicate that a significant proportion of eels entering the Cabot forebay become entrained (90% in 2002, 100% in 2003; Brown 2005, Brown *et al.* 2009). The PAD notes that the study done in 2003 determined that 15 of the 29 test eels were detected at the Hadley Falls Station. However, that study was not designed to assess turbine mortality.

To date, no directed studies of eel mortality at Cabot Station or eel entrainment or mortality at either Station 1 or the NFMPS facility have been conducted. These information gaps need to be filled so resource agencies can assess the relative and cumulative impact of project operations on outmigrating eels and develop adequate passage and protection measures to meet management goals and objectives.

We also note that within the past seven years, the U.S. Fish and Wildlife Service (Service) has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability (CESAR). On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made prior to any new licenses are issued for the projects.

Nexus to Project

The Turners Falls Project operates as a peaking facility, except during periods when inflow exceeds the hydraulic capacity of Cabot Station and Station 1. Silver eels outmigrate during the mid- summer through late fall, a time of year when flows are generally near the maximum operating capacity of the stations. Therefore, the project would be expected to spill infrequently during the silver eel outmigration beyond the nominal amount required in the bypass reach.

Racks at Cabot Station, Station 1, and NFMPS facility are not designed to protect eels from entrainment. At Cabot, the racks have one-inch clear spacing on the top 11-feet, with five-inch clear spacing on the bottom 20 feet of racks. The approach velocity at the racks is approximately 2.0 feet per second at maximum hydraulic capacity. At Station 1, the racks have 2.6-inch clear spacing and an approach velocity of 1.2 feet per second. Eels can readily pass through a 2.6-inch clear space. NFMPS has 48-foot-deep trashracks with six-inch clear spacing over the intake and an approach velocity of 3.5 feet per second at full pumping capacity (15,000 cfs).

As mentioned above, previous studies conducted at Cabot Station documented eel entrainment. Cabot Station has existing downstream passage facilities designed for anadromous species, but studies have documented few eels

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

utilizing the surface bypass (likely because Cabot has a relatively deep, wide intake area). Station 1 has no passage and protection facilities. NFMPS has a seasonally-deployed barrier net to minimize entrainment of Atlantic salmon smolts, but it is only operated from April through June 15 annually. While no studies have been conducted at Station 1 or NFMPS facility, the rack spacing is wide enough to allow for entrainment.

Methodology Consistent with Accepted Practice

In order to understand the movements of outmigrating silver eels as they relate to operations at the Northfield Mountain Pump Storage Facility, Station 1, and Cabot Station, radio telemetry technology should be utilized. Radio telemetry is an accepted technology that has been used for a number of studies associated with hydropower projects, including at the Muddy Run Project (FERC No. 2355).

Studies should be designed to investigate route selection (i.e., entrainment vs. spill) independently from estimation of mortality/injury, because these metrics require different telemetric methodologies. Studies also will likely benefit from data from several seasons (especially route selection studies, which may be more significantly affected by environmental conditions during a given season than mortality/injury studies). It is also envisioned that results from route selection studies can guide design of turbine mortality studies. Therefore, it is proposed, at a minimum, that route selection studies be conducted in multiple years, but mortality/injury studies may be conducted after the first year of route selection studies have been completed.

• **Objective 1: Route Selection**

This study will involve systematic releases of radio-tagged silver phase eels at strategic points above areas of interest, to assess general routes of passage (i.e., via spill, bypass, or turbines). Active downstream migrants should be collected within-basin if possible (i.e., Cabot or Holyoke bypass samplers), but fish sourced from out of basin may be acceptable to meet sample size demands. Experimental fish must meet morphometric (e.g. eye diameter relative to body size) criteria to ensure they are migrant silver phase. Collections should be made within the migratory season (late Aug to mid Oct), and eels should be tagged and released within 7 days of collection.

○ **NFMPS Route Selection Study:**

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Eels will be released at least 5 km upstream of the NFMPS project; releases should be timed so that there is a significant probability that migrating eels will encounter NFMPS during the pumping stage. Radio telemetry antennas will be strategically placed to determine times eels are present within the river reach in the vicinity of the NFMPS intakes, within the intakes themselves, and whether they are entrained into the upper reservoir.

○ **Turners Falls Dam Route Selection Study:**

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Groups of eels should be released during spill and non-spill periods if possible. Tagged eels will be released at least 3 km upstream of the Turners Falls dam but several km below the intake to NFMPS. Telemetry receivers and antennas will be located above and below the dam to assess passage via the following potential routes: entrainment into power canal; passage via spill over the bascule gates; passage via spill through the taintor gates.

Eels from the NFMPS route study not entrained into the NFMPS intake and migrating to the Turners Falls Dam may be used to supplement (but not serve in lieu of) these release groups.

○ **Turners Falls Project – Canal Route Selection Study:**

A minimum number of 50 telemetered eels (e.g., 5 separate groups of approximately 10 eels each) will be required to maximize the data return. Groups of eels should be released during periods of low, moderate, and high generation conditions if possible. Eels will be released in the upper canal (ideally just downstream of the Gatehouse), and allowed to volitionally descend through the canal. Telemetry receivers and antennas will be located within the canal, bypass, channel, and mainstem below Cabot Station to assess passage via the following potential routes: Spillway Fishway attraction water intake

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

(if operational); Station 1 turbines; Cabot Station spillway; Cabot Station bypass; Cabot Station turbines

Eels from the NFMPS and Turners Falls Dam Route Studies not entrained into the NFMPS intake and migrating into the Turners Falls Canal may be used to supplement (but not serve in lieu of) these release groups.

Mobile tracking (i.e., via boat) in river reaches between release sites and several km downstream of Cabot Station will be performed at regular intervals during and after releases to confirm routes and fates of passed fish, or fish lost to follow-up.

Movement rates (time between release and passage) of eels passing the projects by various routes will also be quantified.

The route selection portion of this study should occur in both study years.

- **Objective 2: Spill, Bypass, and Turbine Mortality/Injury Studies**

Spill, bypass, and turbine mortality will be assessed using a radio-telemetric balloon tag method. A minimum number of 50 tagged eels (e.g., 5 separate groups of approximately 10 eels each) will be required at each location (dam bascule gate, dam taintor gate, Cabot Station spillway, Cabot Station bypass, Station 1 and Cabot Station) to maximize the data return. Turbine mortality studies are not required at NFMPS because it is assumed that all entrained fish (including eels) are lost to the Connecticut River system.

For spill mortality sites (dam bascule gate, dam taintor gate, Cabot spillway, Cabot Station bypass), tagged eels will be injected or released into spill flow at points where water velocity exceeds 10 ft/sec, to minimize the possibility of eels swimming upstream into the headpond or canal. Passed balloon-tagged eels will be recovered below areas of spill and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.

For turbine mortality sites (Station 1 and Cabot Station), tagged eels will be injected into intakes of units operating at or near full generation at points where intake water velocity exceeds 10 ft/sec, to minimize the possibility of eels swimming back upstream through the intakes. Passed balloon-tagged eels will be recovered in the tailrace and held for 48 hours in isolated tanks for observation of injury and latent mortality; unrecovered balloon-tagged eels will be censored from the data.

Mobile tracking (i.e., via boat) in river reaches between release sites and several km downstream of Cabot Station will be performed at regular intervals after releases to confirm routes and fates of passed fish, or fish lost to follow-up.

The turbine mortality component of the study should occur in Study Year 2.

Data analyses of route selection and turbine mortality (instantaneous and latent) will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the downstream eel passage study would be moderate to high; silver eels would need to be collected, tagged, and released in several locations over the course of the migration season. Antennas and receivers would need to be installed at the intakes to all stations as well as at the Turners Falls dam spillway and Cabot Station bypass, and monitored regularly. Data would need to be retrieved periodically, then analyzed. A multi-site route selection study conducted by the USGS Conte Lab on the Shetucket River in Connecticut cost

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

approximately \$75,000 for the first year of study. Cost are estimated at \$100,000 per year for the Route Selection studies and \$75,000 per year for the Spill, Bypass, and Turbine Mortality/Injury Studies.

In the PAD, the applicant has identified the need to assess issues related to downstream passage for American eels at the project, but indicates that it intends to rely on information from previously conducted studies and ongoing studies. The Division is not aware of any previously conducted or ongoing studies related to downstream eel passage.

Requested Study No. 9.

Evaluation of Timing of Downstream Migratory Movements of American Eels on the Mainstem Connecticut River

Goals and Objectives

The goal of this study is to better understand migration timing of adult, silver-phase American eels as it relates to environmental factors and operations of mainstem hydropower projects on the Connecticut River.

The objectives of this study are:

- Quantify and characterize the general migratory timing and presence of adult, silver-phase American eels in the Connecticut River relative to environmental factors and operations of mainstem river hydroelectric projects

Resource Management Goals

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

- Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
- Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Eel (Anguilla rostrata) in the Connecticut River Basin* in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

- Protect and enhance eel populations where they currently exist;
- Where practical, restore populations to waters where they had historical abundance;
- Provide effective upstream and downstream fish passage around dams and other barriers within the species’ range in the basin; and
- Comply with all requirements of the Fishery Management Plan of the ASMFC.

Based on these plans, the Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to downstream passage of American eel, the Division’s goals are:

- Minimize current and potential negative project operation effects that could hinder management goals and objectives.
- Minimize project-related sources of downstream passage delay, injury, stress, and mortality in order to maximize the number of silver eels migrating to the spawning grounds.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

Data on timing of downstream migratory movements and rates of American eels in the mainstem Connecticut River are sparse and relatively incomplete. Preliminary data on presence of “eel-sized” acoustic targets have been collected (Haro et al. 1998) within the Turners Falls Project’s Cabot Station forebay that were somewhat confirmed by video monitoring at the Cabot Station downstream fish bypass; however, these were short-term studies, with acoustic monitoring only performed from 17 September to 5 October and video monitoring only conducted between 18 September to 22 October.

Some daily monitoring of the downstream bypass at the Holyoke Dam (canal louver array) was performed in 2004 and 2005 (Kleinschmidt, Inc. 2005, 2006, Normandeau Associates 2007); these studies also were of relatively short duration (spanning from October 5 to November 10 in 2004 and September 9 to November 11 in 2005) and the sampler was only operated at night.

To date, no other directed studies of eel migratory movements have been conducted at any location on the Connecticut River mainstem. This information gap needs to be filled, as it relates directly to when downstream passage and protection measures need to be operated.

We also note that within the past seven years, the U.S. Fish and Wildlife Service (Service) has received two petitions to list the American eel under the Endangered Species Act. The first petition was received on November 18, 2004. On July 6, 2005 the Service issued a substantial 90-day finding on the petition and initiated a 12-month status review that concluded on February 2, 2007 with a finding that listing was not warranted. The second petition was filed on April 30, 2010 by the Council for Endangered Species Act Reliability. On September 29, 2011 the Service issued a substantial 90-day finding and initiated a 12-month status review. The Service is still accepting new American eel information for the ongoing status review. The Service also is currently in settlement negotiations with CESAR on their legal complaint that the Service failed to complete the 12-month finding within the statutory timeframe. Although the date for completion of the Service's 12-month finding on the latest petition is uncertain, it is likely that it will be made before any new licenses are issued for the projects.

Nexus to Project

The timing of downstream migration of adult eels is poorly defined for the Connecticut River; therefore the general effects of hydroelectric project operations on eel survival to the ocean are unknown. Although separate study requests have been submitted to address project-specific downstream passage route selection, delays, and mortality of eels, general characteristics of river flow and environmental conditions may have significant relationships with project operation and eel migratory success and survival. For example, eels may tend to move immediately before or during periods of significant precipitation (or consequently river flow); times at which projects may be generating at maximum capacity or spilling, which may (or may not) present a higher passage risk to eels. Conversely, periods of low flow may be associated with a significant proportion of total river flow passing through turbine units, which present additional (or different) passage risk to eels. If discrete conditions which promote eel downstream migration are known, it may be possible to take actions with respect to project operations which reduce or minimize passage risk; i.e., operation of a bypass, reduction of intake approach velocities, directed spillage through a “safe” route, etc. These studies should provide baseline information on river-specific downstream migration to predict when silver-phase eels are expected to be migrating in the mainstem Connecticut River, from which project operations could be modified to minimize passage risks.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The studies are proposed for a single or multiple sites; the results will be relevant to all sites on the Connecticut River mainstem.

Methodology Consistent with Accepted Practice

Quantification of downstream movements of American eels in river systems requires systematic sampling of migrants throughout the migratory season. This can be accomplished with traditional active trapping methods; i.e., fyke or stow net sampling, weirs, or eel racks, but these methods are technically challenging on larger mainstem rivers, due to the scale of flows that need to be sampled, difficulties in operation throughout all flow conditions, and high debris loading during fall flows. Passive monitoring of migrant eels using hydroacoustic methods offers an alternative to active trapping. However, passive monitoring requires verification of potential acoustic targets with some level of active (collection) or visual (traditional optical or acoustic video) sampling.

Two potential locations offer opportunities to conduct simultaneous passive and active sampling: the Cabot Station (Turners Falls project) canal/forebay and the Holyoke Dam forebay and canal louver/bypass system. Each location possesses a route of downstream passage which conducts a significant proportion of river flow (Cabot canal and Holyoke forebay or canal), and each has a proximal bypass equipped with a sampler so that fish can be concentrated/collected from the passage route and identified to species. Project operations do influence the relative proportion of flow (and thus numbers of downstream migrant eels) in each passage route, so numbers of eels sampled in each route represent only a proportion of the total number of eels migrating downstream within the entire river. Because the absolute proportion of eels using a specific route at any one time is unknown, numbers of eels quantified within a route must serve as a relative index of the degree of migratory movement.

This study shall quantify eel movements in either one, or preferably both, locations for two consecutive years (since environmental conditions strongly influence migratory timing of eels, which can vary significantly from year to year; Haro 2003). Eels will be quantified using methods similar to Haro et al. (1999), by continuously monitoring a fixed location at the projects with hydroacoustics. Because eels tend to concentrate in areas of dominant flow (Brown et al. 2009, EPRI 2001), the zone to be monitored should pass a dominant proportion of project flow throughout most periods of operation (i.e., forebay intake area). Hydroacoustic monitoring shall encompass the entire potential migratory season, beginning in mid-August and ending in mid-December, and shall operate 24 hours per day. Data will be recorded for later processing and archiving.

Systematic active quantification of eels at downstream bypass samplers shall be performed simultaneously with passive hydroacoustic monitoring, to verify presence of eels and relative abundance of eel-sized hydroacoustic targets from the hydroacoustic data. Although daily operation of the bypass sampler could be performed, a more comprehensive technique is to monitor eels entering the bypass with an acoustic camera (i.e. DIDSON, BlueView, etc.). The acoustic camera will afford positive visual identification of eels as they enter the bypass, which is a concentration point for migrating eels. Acoustic camera monitoring will also allow monitoring to be performed 24 hours a day, and will be relatively unaffected by water turbidity (which influences effectiveness of traditional optical video monitoring). The acoustic camera system will be operated during the same time period as acoustic monitoring, and images will be recorded for later processing and archiving.

Data analyses of hydroacoustic, acoustic camera, bypass sampling, and environmental/ operational data will follow standard methodology.

Project operation (flows, levels, gate openings, number of units operating and operation level) and environmental conditions (river flow, temperature, turbidity, air temperature, precipitation) will be monitored regularly (hourly measurements if possible) throughout the duration of the studies.

These methodologies are consistent with accepted practice.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the downstream migrant eel migratory timing study would be moderate, given the level of cost for instrumentation, deployment, and data review/analysis. Cost is estimated at \$50,000 per year for the study.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The applicant did not propose any studies to meet this need in the PAD.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 10.
Three-dimensional Computational Fluid Dynamics (CFD) Modeling in the Vicinity of Fishway Entrances and Powerhouse Forebays

Goals and Objectives

The goal of this study is to determine the flow field conditions that exist in and around the fishway entrances, and upstream of both Turners Falls powerhouses (Station 1 and Cabot). The information from this request is meant to be coupled with data from telemetry studies such that a comprehensive understanding of fish behavior is developed.

The objective of this study is to develop a series color contour maps of velocity magnitude and direction at discharges that have been agreed upon by the resource agencies and the licensee. With respect to upstream passage, the results will show approach velocities and orientation within the approach zone of the fish that may create a response in fish. This information can be coupled with telemetry data (from the requested telemetry studies) and passage counts to understand which conditions are optimal for guiding migrating fish to the fishway entrances and for stimulating fishway entry.

With respect to downstream migration, the results will show velocities and orientations in front of each powerhouse. At Cabot Station, the results will indicate to what degree, if any, flow directs downstream migrating fish towards the surface bypass weir. At Station 1, we will have an improved understanding of the magnitude of velocity in front of the turbine intakes.

Resource Management Goals

The management goals of this study request are to obtain information that will help assist in designing effective upstream fishways for upstream migrating trust species and to reduce impingement, entrainment and delay for downstream migrating fish. CFD models are a relatively cost effective way to analyze existing and future conditions. As such, changes in the amount of attraction water, changes in which turbines are operating, and which spillway gates are releasing water can all be examined. As stated, the results from this study are meant to be used along with the data generated from the telemetry study. The combined analysis from these two data sources can help assess which flow conditions are most advantageous for migrating trust species to enter the fishway under current and proposed conditions.

As for downstream migration of adult and juvenile shad, and adult eel, the results from the models will reveal flow magnitude and direction in front of each powerhouse. Given the limited information that currently exists on survival through Cabot and Station 1, our management goal is to direct as many downstream migrating fish as possible towards the uniform acceleration weir and downstream bypass. With respect to upstream passage, we want to maximize the number of fish that find and enter the fishway entrances

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information and the Need for Additional Information

To date, no CFD modeled data exist in front of either fish ladder, nor do they exist in front of either powerhouse. Some preliminary modeling has been done downstream of the gatehouse, but changes to the gatehouse entrances would require updated modeling. It is our understanding that the licensee has worked with the firm Alden Research Laboratory, Inc., to develop a CFD model of the upper end of the power canal and that elevation survey data from the power canal also are available. Detailed two-dimensional movement data on shad are available from observations made between 2003 to 2005 and 2010 to 2012. By coupling and analyzing these two data sets, flow and fish movement, we believe this will have substantial benefits to our management efforts.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Nexus to Project

The Turners Fall Project has direct impacts to upstream and downstream migrating shad and eel. When designing upstream passage structures, a site assessment is critical. The development of these models will give resource agencies valuable information into the hydraulic cues which may elicit a response from upstream migrants. For downstream passage, the U.S. Fish and Wildlife Service has approach velocity guidelines; the output from these models would inform the resource agencies under what conditions appropriate approach velocities are being met and when they are being exceeded.

With respect to upstream migration, the auxiliary water system (AWS) plays a critical role in determining whether or not fish are attracted to the entrance. The results from this study would allow us to assess how well the AWS is performing and under what conditions it attracts the most fish.

With respect to downstream migration, the development of a CFD model under existing conditions also informs the design of future modifications and improves the survivability of downstream migrating shad and eel.

The CFD models for the spillway fishway and gatehouse fishway should be developed as part of year one studies and it would be preferable to have them completed prior to year one field studies in spring 2014. It would be useful to have the gatehouse area CFD modeling completed as soon as possible to begin comparing hydraulic conditions to the two-dimensional shad location data from prior studies. This analysis may provide information on adjustments to canal operations or structures that can subsequently be analyzed.

Understanding the entrance conditions of the spillway fishway under a range of spill conditions would be informative as we evaluate the spillway fishway entrances. If developed prior to the year one upstream shad telemetry studies, it would provide information on spill gate settings that would likely best achieve entrance and ultimately passage. Further work with the model after year one studies could evaluate changes in ladder entrance or spill conditions that could improve passage and be tested with year two telemetry, video and/or count data.

CFD modeling of the flows leading to the canal via the gatehouse and the Cabot Station and Number 1 Station forebays would have value in interpretation of year one downstream passage telemetry results, but would not need to be completed prior to the year one telemetry, downstream juvenile shad and downstream eel passage studies, as those studies will provide the context for how and where shad and eels are passing the project and how successful passage is. The CFD modeling could then be focused on the locations indicated as important based on the field studies and could assess changes to structures or operations that could be evaluated in the model. Promising alternatives could then be tested in year two studies.

Methodology Consistent with Accepted Practice

A three-dimensional CFD model has become an increasing common standard of analysis at hydro-electric projects around the nation. Within the northeast region, we have seen these types of models developed at the Holyoke (P-2004), Brunswick (P-2284), Shawmut (P-2322), Milford (P-2534) and Orono (P-2710) projects. We would expect to engage with the licensee in terms of determining the appropriate area and flows to be modeled. We expect that the spatial extent of the model at each study site will vary. Given the large number of ways that output from these models can be presented and the near infinite number of flows that could potentially be modeled, we would expect to consult with the licensee to reach agreed upon modeling efforts and scenarios to be examined.

Level of Effort/Cost, and Why Alternative Studies Will Not Suffice

The cost of developing, running and testing a CFD model can vary tremendously; one large variable in determining the cost is based on the amount of existing bathymetric data to which the Applicant currently has access. We roughly estimate that the cost of each CFD model could run as high as \$50,000, assuming no bathymetric data currently exist. Proactive communication with resource agencies will reduce the cost and iterative effort. Given the level of effort that has occurred at other projects that have proposed to amend their license, we see the level of effort requested here as reasonable, given that the Applicant is seeking a renewal of its license.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 11.

Computational Fluid Dynamics (CFD) modeling of the Northfield Mountain Pumped Storage Project Intake/Tailrace Channel and Connecticut River Upstream and Downstream of the Intake/Tailrace.

Goals and Objectives

The goal of this study is to determine the potential impacts of the Northfield Mountain Pump Storage Project (NMPS) operations (pumping and generating) on: (1) the zone of passage for migratory fish near the turbine discharge/pump intake; (2) natural flow regimes in the area of the Connecticut River immediately upstream and downstream of the project; and (3) the potential for fish entrainment during pumping operations.

Specific objectives of the study include:

- Develop a CFD model of the NMPS intake and tailrace channel, along with the full width of the Connecticut River upstream and downstream of the discharge.
- Model flow characteristics upstream and downstream of the project under existing project operations (pumping and generating) and at several representative river flow levels, as well as proposed operations such as those proposed in section 3.4.4 of the PAD, and any other modifications under consideration, to assess potential impacts to fish and wildlife resources
- Assess velocities and flow fields at and in proximity to the NMPS intake/discharge structure when pumping or generating and their potential to interfere with fish migration, create undesirable attraction flows and result in fish entrainment.
- Assess the potential for velocity barriers in the mainstem river resulting from pumping and generation flows at the project, alone or in combination with generation flows from the upstream Vernon Project and operations at the Turners Falls Project.
- Assess the potential of a mainstem instream local flow reversal associated with pumping operations to impact migrating fish.
- Model and then evaluate flow characteristics under alternative project operations with potential measures to avoid, minimize, or mitigate impacts to fish and wildlife resources.

Resource Management Goals

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to aquatic resources, the Division's goals are:

- Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Provide an instream flow regime that meets the life history requirements of resident and migratory fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize current and potential negative project operation effects on water quality and aquatic habitat.
- Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing at the Cabot Station spawning and rearing site.

Instream flow is an important riverine habitat characteristic that can have a great impact on aquatic habitat for fish, wildlife, and plants. Flow is an important directional guidance cue for instream navigation and attraction to fishway entrances for migratory fish.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

No project specific information exists that will allow for a comprehensive assessment of existing project operations (pumping and generating flows) on Connecticut River flows and on fish and aquatic organisms in the project area upstream and downstream of the project in the Connecticut River. Preliminary results from an ongoing study of radio-tagged American shad by the USFWS and USGS Silvio O. Conte Anadromous Fish Research Center indicate that shad are exposed to the intakes and some individuals spend substantial amounts of time in the vicinity of the intakes. The PAD does not contain any information or tool that will allow for predictions of impacts of alternative project operations, or potential mitigation measures to protect or enhance aquatic fish and wildlife resources.

Nexus to Project Operations and Effects

Existing project operations have a direct impact on instream flow and aquatic habitat in the pump/discharge area of the Connecticut River. The PAD in section 3.2.2 says that the discharge at the trash racks when operating at full capacity is 20,000 cfs and maximum pumping conditions are 15,200 cfs. Annual flow duration curves shown for below the Vernon Dam submitted in the PAD section 4.3.1.2 (for years 1944-1973; recent and near project flows are not available; see p. 459) indicate that river flows are $\leq 20,000$ cfs more than 85% of the time. Flows released from the project must therefore influence flow patterns and velocities in the Connecticut River, particularly at flows below some unknown threshold level.

Recreational users of the Connecticut River in the Turners Falls impoundment have anecdotally described flow reversals in the mainstem river. Discharges from the project could potentially be larger than river flows or at least act like a major tributary to the Connecticut River. Project flows may influence the availability and extent of upstream and downstream migration zones, or may confuse fish and delay migration.

Methodology Consistent with Accepted Practice

CFD modeling is consistent with generally accepted practice, and has been used to assess proposed modifications to the Holyoke Project (FERC No. 2004) fish passage facilities, upstream of the intakes and downstream of the dam, as well as at hydroelectric projects on the Susquehanna River to assess existing and proposed project operations, and develop mitigation measures for fish and wildlife resources.

A study plan that describes the specific modeling tools to be used, the amount of bathymetric data to be gathered, the geographic scope of the assessment and the flow conditions to be modeled will need to be developed in consultation with the Division and other parties.

Level of Effort/Cost, and Why Alternative Studies will not suffice

This study will require a detailed elevation map of the study area upstream and downstream of the NMPS intake structure. Some information already exists in historic construction files for the project and past hydraulic analyses. Additional bathymetric data likely will need to be collected in the field using standard survey techniques. The CFD computer program will need to simulate existing project operations as well as accommodate all potential variations of pumping and generating, and static operation.

No project-specific instream flow analysis tool has been developed for the NMPS that will allow for assessment of existing operations and alternative operational impacts on instream flow and aquatic habitat for fish and wildlife resources. The computer model, once built, can be used to simulate flow conditions in the vicinity of the project during migratory fish passage and can be used together with behavior studies (i.e., telemetry studies and entrainment studies requested herein) to assess the impacts of varying project operations or potential mitigation operations and measures on fish migration and aquatic habitat. We know of no other tool that will provide for these types of assessments. Cost is expected to be moderate to high.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 12.

Entrainment of Migratory and Riverine Fish from the Connecticut River into the Northfield Mountain Pump Storage Project.

Goals and Objectives

The goal of the study is to determine the impact of Northfield Mountain Pump Storage Project (NFMP) during the pumping cycle on entrainment of juvenile American shad, adult shad, adult American eel, and riverine fish, including early life stages.

The objective of the study is to quantify the number of resident and migratory fishes entrained at the NFMP intake on an annual basis in order to evaluate potential impacts to riverine fish populations in the Turners Falls pool and diadromous fish migrants moving through the project area. This will be accomplished through a combination of hydroacoustic monitoring and netting using various gear types to quantify and identify species of different life stages.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually. (Table 1)
- Achieve annual passage of 40 to 60% of the spawning run (based on a 5-year running average) at each successive upstream barrier on the Connecticut River mainstem.
- Maximize outmigrant survival for juvenile and spent adult shad.

Based on the CRASC plan, the Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

The Atlantic States Marine Fisheries Commission has developed two documents related to the management of American eel:

- Interstate Fishery Management Plan for American Eel. April 2000. Atlantic States Marine Fisheries Commission.
- Addendum II to the Fishery Management Plan for American Eel. Atlantic States Marine Fisheries Commission. Approved October 23, 2008. 8 pp.

Objectives of the management plan include: (1) protect and enhance American eel abundance in all watershed where eel now occur; and (2) where practical, restore American eel to those waters where they had historical abundance but may now be absent by providing access to inland waters for glass eel, elvers, and yellow eel and adequate escapement to the ocean for pre-spawning adult eel.

Addendum II contains specific recommendations for improving upstream and downstream passage of American eel, including requesting that member states and jurisdictions seek special consideration for American eel in the FERC relicensing process.

In addition, the Connecticut River Atlantic Salmon Commission (CRASC) developed *A Management Plan for American Eel (Anguilla rostrata) in the Connecticut River Basin* in 2005. The goal of the plan is “to protect and enhance the abundance of the American eel resource to ensure its continued role in the Connecticut River Basin ecosystem...” Management objectives in the plan include the following:

- Protect and enhance eel populations where they currently exist;
- Where practical, restore populations to waters where they had historical abundance;

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Provide effective upstream and downstream fish passage around dams and other barriers within the species' range in the basin; and
- Comply with all requirements of the Fishery Management Plan of the ASMFC.

Specific to resident riverine and migratory fish entrainment, the Division's goals are:

- Minimize current and potential negative project operation effects such as turbine entrainment that could hinder management goals and objectives.
- Minimize project-related sources of mortality to resident and migratory fishes in order to restore natural food web interactions and ecosystem functions and values.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a fish and wildlife resource agency.

Existing Information

Limited project-specific information exists regarding entrainment of fish and aquatic organisms at the NFMPS. As part of a Memorandum of Agreement between then-owner Northeast Utilities Service Company (NUSCO) and regulatory agencies (including the Division), NUSCO conducted studies to determine the impact of NFMPS on anadromous fishes, including Atlantic salmon, American shad, and blueback herring. Results of a pilot study conducted in the fall of 1990 indicated that trap netting at the intake was ineffective at collecting fish. Gill netting and boat-shocking did result in collection of some juvenile shad, but further refinement in both methods was recommended to improve effectiveness. A total of 78 fish were collected at the intake (77 of which were American shad) by gill netting and 11 shad were collected by boat electrofishing. Hydroacoustic monitoring was deemed an effective method for monitoring entrained fish during pumpback operation. Hydroacoustic sampling over a two-week period (September 12-27, 1990) produced hourly entrainment estimates that cumulatively equaled 14,816 fish. Based on the results of the pilot study, NUSCO developed a two-year plan to quantitatively determine the number of shad and salmon entrained at NFMPS station. In 1992, an entrainment study targeting juvenile American shad life stages was conducted in the lower (mainstem river) and upper reservoirs of NFMPS. The study used several gear types to quantify egg through juvenile shad densities in different areas. Entrained juveniles were sampled using an upper reservoir net. Pumping operations were modified to only run three (77% of sample time) and sometimes two (23% of sample time) of the station's four units during the study and effort was limited to a total of 80 hours over a period spanning 9 August through 27 October (80 days). An estimated total of 1,175,900 shad eggs, 2,744,000 yolk-sac larvae, 10,525,600 post yolk-sac larvae, and 37,260 juveniles were reported entrained.

There are no reliable data on the timing, magnitude and duration of entrainment of larval riverine fishes in the NFMPS area. Unlike anadromous shad and river herring, riverine species occurrence and susceptibility relative to space and time exposure windows to NFMPS pumping are undocumented. The complete lack of any long-term fish population monitoring data for riverine species in the Turners Falls impoundment leaves questions unanswered on the types and extent of impacts to these populations that may be linked to the near daily cycling of river water up and down through the NFMPS operations system. As a starting point, it is necessary to obtain baseline data on project operation impacts for all species potentially impacted by NFMPS. An additional study request seeks to obtain a more accurate documentation of all fish species inhabiting or utilizing the Turners Falls impoundment.

Nexus to Project Operations and Effects

Entrainment of fish and aquatic organisms associated with water withdrawal and hydroelectric operations has been documented to result in injury or death of entrained organisms. Migratory and resident fish pass through the project area directly in front of the pump intakes. These organisms may be entrained and thus exposed to passage through the project pumps and reservoir supply tubes. How far from the intake these species and life stages may be drawn into the intake on a pumping cycle or how susceptible they are to the repeated daily cycles of pumping and discharge, and how these factors vary in relation to habitat and river conditions are unknown. Survival of fish

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

subjected to entrainment on the pumping cycle is unknown, but regardless of whether fish survive the pumping process, they are lost to the Connecticut River system. Depending on the species, life stages, and numbers entrained, this loss could impact the ecosystem productivity of the Turners Falls pool and may hinder restoration goals for diadromous fishes.

Previous entrainment studies have been conducted at the project. Those studies, which were done 20 years ago, documented entrainment of American shad and Atlantic salmon at the project, including over 13 million yolk sac and post-yolk sac larvae of American shad. This level of entrainment is cause for concern, not only due to the resultant loss of potential adult returns, but for the important role early life history phases and juveniles play in their ecological contributions to the river system (e.g., trophic interactions).

No entrainment studies for other species of fish have been conducted at the project. The unknown extent of other riverine species ichthyoplankton entrained by the NFMPS requires evaluation. Studies conducted in 1969 and 1970 at the Muddy Run Pumped Storage Station documented significant entrainment of eggs and larval fish. In June and July of 1970, 5.3 million eggs and 56.6 million larvae were entrained (Snyder 1975). Muddy Run and NFMPS are of a similar size and both use a river as the lower reservoir. It is anticipated that a considerable number of eggs and larvae will be entrained by the NFMPS.

Since the previous studies were conducted, operations at the NFMPS facility have changed (e.g., the project increased the efficiency of its turbines, and raised the pumping capacity from 12,000 cfs up to 15,000 cfs), as have river conditions (e.g., Vermont Yankee has increased its thermal discharge and the Vernon Project has increased its station capacity). Further, the PAD indicates that FirstLight will evaluate the feasibility of utilizing an additional 3,009 acre-feet of storage capacity to generate an additional 1,990 MWhs (this represents a 23% increase over existing storage and stored generation levels). While not specified in the PAD, increasing storage and generation would mean longer periods of both pumping and generation at NFMPS. In addition, anticipated improvements in fish passage at the Turners Falls Project will result in increased juvenile production above the NFMPS. These factors, individually or cumulatively, could increase the potential for entrainment at NFMPS station.

Methodology Consistent with Accepted Practice

Previous studies used varying methodologies for determining entrainment. The 1990 study concluded that hydroacoustic monitoring at the intake was a viable method for determining entrainment of later life stages, but does not allow for identification of the species being entrained. While trap netting was ineffective at collecting fish near the intake, gill netting and boat shocking did capture some fish. Both may prove to be viable sampling methods; however it is likely that additional testing and gear refinement will be necessary.

The 1992 study used nets at the pump discharge location into the upper reservoir to collect entrained fish. Testing showed that this method was only 10% efficient. Plankton netting in the nearfield area of intake was used to estimate entrainment of ichthyofauna. It is likely that a combination of methods would provide the most reliable results (e.g., hydroacoustic monitoring at the racks during pumpback operations, variable gear sampling in the vicinity of the intake immediately prior to initiation of pumpback operations to determine species composition, and plankton netting in the nearfield area of the intake to obtain information on entrainment of ichthyofauna). As these methodologies have previously been utilized at the site, they are consistent with accepted practice.

Although a previous entrainment study was conducted, the Division believes it should be repeated, using a modified study design. The 1992 study only collected a total of 330 juvenile shad over a three-month period (resulting in an overall estimate of 37,260 juveniles entrained, after accounting for poor net efficiency); whereas the hydroacoustic study conducted in 1990 estimated nearly 15,000 fish in 15 days (while these fish were not identified, 77 of the 78 fish collected at the intake during the study were juvenile shad). It also should be noted that in the 1992 study, juvenile shad were collected on the first day of sampling, indicating that the sampling did not begin early enough, which would mean the results are an underestimate of the number of juvenile shad that were actually entrained. In 1990, 27,908 adult shad passed the Turners Falls gatehouse, while in 1992 over 60,000 shad passed gatehouse. The fact that the numbers entrained were so variable between study years argues for repeating the study, using a combination of previously-used methodologies.

The study will require deployment of at least five hydroacoustic transducers (one per rack face and one offshore). These transducers would be operated during every pumping cycle from April 15 through May 14 to assess riverine

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

fish entrainment, from May 15 through July 15 for spent adult shad, and from July 16 through November 30 for entrainment of adult silver eels, juvenile American shad, and riverine fishes. Concurrent field sub-sampling at the intake to determine species composition would need to occur.

Sampling for planktonic fish larvae should capture early spring spawning species (white suckers) through later season centrarchid species (bass and sunfish). Active plankton trawl surveys should utilize a sampling design that adequately captures temporal and spatial changes in water pumping cycle (i.e., early start-up is local water, later cycle pumping is drawn in from both upstream and downstream habitat areas).

Level of Effort/Cost, and Why Alternative Studies will not suffice

We know of no other tool that will provide for this type of assessments for all fish species and organisms that may pass through the project. Cost and effort are expected to be high. The applicant did not propose any studies to meet this need in the PAD.

Requested Study No. 13.

**Model River Flows and Water Levels Upstream and Downstream from the Turners Falls Project Dam
Generating Stations and Integration of Project Modeling with Upstream and Downstream Project Operations**

Goals and Objectives

Develop a river flow model(s) that are designed to evaluate the hydrologic changes to the river caused by the physical presence and operation of the Turners Falls Hydroelectric Project and the interrelationships between the operation of all five hydroelectric projects up for relicensing (i.e., P-1889 Turners Falls Hydroelectric Project, P-2485 Northfield Mountain Pumped Storage, P-1904 Vernon Hydroelectric Project, P-1855 Bellows Hydroelectric Project, P-1892 Wilder Hydroelectric Project) and river inflows. The flow studies should assess the following topics:

- Conduct quantitative hydrologic modeling of the hydrologic influences and interactions that exist between the water surface elevations of the Turners Falls Project impoundment and discharges from the Turners Falls Dam and generating facilities and the upstream and downstream hydroelectric projects. Data inputs to and outputs from the model(s) should include:
 - Withdrawals from the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project, FERC No. 2485,
 - Discharges to the Turners Falls impoundment by the Northfield Mountain Pumped Storage Project,
 - Discharges into the Turners Falls impoundment from the Vernon Project, FERC No. 1904 and other sources.
 - Existing and potential discharges from the Turners Falls Project generating facilities and spill flows.
 - Existing and potential water level fluctuation restrictions (maximum and minimum pond levels) of the Turners Falls impoundment and downstream flows from the project
 - Existing and potential required minimum flows and/or other operation requirements at each of the four upstream projects.
 - Minimum discharge flows ranging between 2,500 and 6,300 cfs in the bypass reach from April 15th through June 22nd to support spawning, rearing, and outmigration of shortnose sturgeon at Rock Dam.
 - Document how the existing and potential outflow characteristics from the four upstream projects affect the operation of the Turners Falls Project including downstream flow releases and Turners Falls impoundment levels.
 - Assess how the operation of the existing Turners Falls Project and upstream projects affect Holyoke Project (P-2004) operations including:
 - How Turners Falls Project flow fluctuations affect Holyoke impoundment water levels, with emphasis on the influence on the water levels on listed Puritan tiger beetle habitat at Rainbow Beach in Northampton, MA and assess what changes would be needed in Turners Falls operations to stabilize water levels at Rainbow Beach.
 - How Turners Falls Project operations affect Holyoke Project discharges and what changes in Turners Falls operations would be needed to reduce fluctuations in the discharges from the Holyoke Project.
- A. To the extent predictable and practical, incorporate the potential effects of climate change on project operations over the course of the license.

Determine the extent of alteration of river hydrology caused by operation of the project and the interactions between upstream project operations, Turners Falls operations and downstream operations at the Holyoke Project. The models will provide necessary information on what changes can be made to each of the five project's flow releases and/or water levels restrictions, and how those changes affect downstream resources.

Specifically, for the Turners Falls Project continuous minimum discharge flows in the Turners Falls bypass reach need to be no less than 2,500 cfs during shortnose sturgeon spawning, rearing, and outmigration (April 15th – June

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

22nd). Incorporating these parameters into the model will inform what changes, if any, need to be made to operations of upstream projects to accommodate such flows.

As other specific modifications of the operations of each of the projects are identified based on results of other requested studies, these desired conditions will need to be input into the models to assess how each change affects that project and other project operations and the implications of those changes on other resources and/or the ability to achieve desired operational changes at other projects.

Resource Management Goals

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.
- Assist FERC to ensure that the continued operation of the facility is not likely to jeopardize the continued existence of shortnose sturgeon.

Specific to aquatic resources, the Division's goals are:

- Protect, enhance, or restore, diverse high quality aquatic and riparian habitats for plants, animals, food webs, and communities in the watershed and mitigate for loss or degradation of these habitats.
- Provide an instream flow regime that meets the life history requirements of resident fish and wildlife (including invertebrates such as freshwater mussels) throughout the area impacted by Project operations.
- Minimize current and potential negative project operation effects on water quality and aquatic habitat.
- Ensure that project operations are not likely to jeopardize the continued existence of shortnose sturgeon.
- Avoid or minimize the current negative effect of project operations on shortnose sturgeon spawning and rearing within the Montague spawning area (i.e. Rock Dam and Cabot Station spawning sites and associated early life stage rearing areas).

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is resource agency.

Existing Information

Available information in the PAD does not indicate how project operations have altered downstream hydrology, which may affect resident and migratory fish, macroinvertebrates, rare, threatened, and endangered species, aquatic plants and other biota and natural processes in the Connecticut River from below the Vernon Dam downstream to the Holyoke Dam.

Information in the PAD also does not reflect data analyzed in Kynard et al. 2012, which identifies minimum discharge thresholds for shortnose sturgeon spawning and rearing at the Rock Dam spawning site. Spawning success was observed at Rock Dam when discharge was between 2,500 cfs and 22,000 cfs during the spawning period (April 27–May 22nd) (Kynard et al. 2012, chapter 3). In 1995 at the Cabot spawning area, the greatest level of spawning and spawning success occurred (i.e., 21 late stage females present, 342 early life stage captured, spawning period was 17 days) even though no spawning was detected at Rock Dam (Kynard et al. 2012, chapter 3). Discharges in 1995 at Rock Dam had dropped below 2,500 cfs by March 26th (Kynard et al. 2012, chapter 3), showing that even though 1995 saw the largest number of pre-spawning adults, none spawned at Rock Dam. This may indicate the need to have adequate flow well in advanced of spawning. Discharge reductions at the Rock Dam site that occurred during spawning caused females to leave the spawning cite and not return even if flow increased to acceptable levels later during the spawning period. Researchers observed that substrate did not change during

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

fluctuating flows and thus cessation of spawning is likely due to velocities falling below the range preferred by females. Given the current flow dynamics at Rock Dam, spawning does not occur most years (Kynard et al. 2012, chapter 3). These data represent the best available scientific information and indicates that the current minimum flow thresholds at the project are not adequate for the protection of endangered shortnose sturgeon. All modeling efforts described above must incorporate the identified minimum flow and temporal parameters.

Nexus to Project

The Turners Falls Project is currently operated with a seasonally-varying minimum bypass flow (400 cfs from 5/1 through 7/15, then 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flow below the projects of 1,433 cfs. The project operates as a daily peaking project, often with large, rapid, daily flow fluctuations between the minimum and project capacity (15,928 cfs) and fluctuations in headpond elevation (175' to 186' MSL). These changes affect biotic habitat and biota upstream and downstream of the project. Project operations and potential changes to operations to mitigate impacts are influenced by inflows and operations of upstream peaking projects and the Northfield Mountain Pumped Storage Project operations and potential changes in operations of each project could affect the ability to achieve desired operational changes at other projects. Results of river flow analyses will be used to develop flow-related license requirements and/or other mitigation measures.

Methodology Consistent with Accepted Practice

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess implications of project operations on the river environment.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Level of effort and cost of model development are expected to be moderate but to be valuable in developing license conditions, the model(s) will need to be run under various scenarios throughout the relicensing process to assess the implications of changes to the operations of each project on other projects and other resources. Therefore, ongoing consultation and re-running of the model(s) are likely to be needed throughout the relicensing process. The modeling exercise will also require coordination and cooperation between First Light and the upstream licensee to assure that the model inputs and outputs can be accurately related.

We would anticipate that the expected level of effort and anticipated costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., Conowingo, FERC No. 405).

Requested Study No. 14.
Impacts of the Turners Falls and Northfield Mountain Pumped Storage Project Operations on Tributary and Backwater Area Access and Habitats

Goals and Objectives

One goal of this study is to determine if water level fluctuations from the Turners Falls and Northfield Mountain Pumped Storage projects result in a barrier(s) to fish movement in and out of tributaries and backwaters to the impoundments and riverine reaches below dams.

A second goal is to determine if water level fluctuations in the Turners Falls and Northfield Mountain Pumped Storage project impoundments impact water levels, available fish habitat and water quality in tributaries and backwaters to the impoundments and riverine reaches below dams, and if impacts are found, to ascertain how spatially far reaching they are and develop mitigation measures.

Results of this study may also be used to help determine the adequacy of existing downstream minimum flow requirements.

Specific objectives include:

- Conduct a field study of tributaries and backwaters, including water velocity and habitat data where appropriate, to evaluate potential impacts of impoundment fluctuation on fish access to tributaries and backwater areas. The study should also evaluate if changes in impoundment fluctuation range would mitigate for any identified impacts and if other mitigative measures would improve access.
- Conduct a field study to examine potential impacts of impoundment fluctuations on water levels, available habitat and water quality in tributaries and backwaters. The evaluation should also evaluate if changes in impoundment fluctuation range would mitigate for identified impacts and if other mitigative measures would lessen these impacts.

Resource Management Goals

This requested study will help promote tributary and backwater access and protect valuable fish habitat and maintain appropriate water quality conditions for diadromous and riverine fish species in project-affected areas. Maintaining connectivity between the mainstem of the Connecticut River and tributaries and backwaters is vital to the fish populations in these systems, as many fish species utilize these areas for spawning, rearing, refuge, and feeding.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is resource agency.

Existing Information

To our knowledge, limited information exists related to this requested study.

Nexus to Project

Project operations have the potential to impact fish species life history requirements, biological interactions, and habitat quantity and quality. For example, water level changes due to project operations could create conditions that could impede free movement of fish between tributaries/backwaters and the mainstem of the Connecticut River, thus limiting access to spawning habitat and/or growth opportunities. Additionally, water level changes could also alter tributary and backwater fish habitat quality, quantity, and also water quality, thus decreasing productivity and available habitat.

Methodology Consistent with Accepted Practice

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Common tools to evaluate water level impacts would be used including: bathymetric mapping, substrate, depth and velocity measurements, and water quality information (dissolved oxygen, temperature, turbidity, and pH). Studies should be conducted throughout the year.

The study area for tributary and backwater fish sampling should cover all tributaries and backwaters within the project-affected areas of the Turners Falls and Northfield Mountain Pumped Storage projects. A second year of study may be required if first year data collection is limited due to environmental or other conditions, or if river discharge in the first year prove to be atypical (outside of 25-75th percentile of average weekly flow values) during the study period.

Level of Effort/Cost, and Why Alternative Studies will not suffice

First Light does not propose any studies to meet this need. Estimated cost for the study is moderate.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 15.
Impacts of the Turners Falls and Northfield Mountain Pumped Storage Projects on Littoral Zone Fish Habitat and Spawning

Goals and Objectives

The goal of this study is to determine if project operations and water level fluctuations in the Turners Falls Project impoundment negatively impact anadromous and resident fish. This study complements a separate study request specific to American shad spawning and also on habitats affected by water level manipulations.

Specific objectives include:

- delineate, quantitatively describe (e.g., substrate composition, vegetation type and abundance), and map shallow water aquatic habitat types subject to inundation and exposure due to project operations, noting and describing additional areas where water depths at lowest operational range are wetted to a depth less than one foot (flats, near shore areas, gravel bars, etc. with very slight bathymetric change);
- conduct analyses of the impacts of normal operations and the maximum permitted reservoir fluctuation range on the suitability of littoral zone habitats for all life stages of target species likely to inhabit these areas;
- conduct field studies to assess timing and location of fish spawning;
- conduct field studies to evaluate potential impacts of impoundment fluctuations on nest abandonment, spawning fish displacement, and egg dewatering; and
- evaluate potential impoundment fluctuation ranges and how implementation of such changes would mitigate for identified impacts.

Resource Management Goals

The mission of the Massachusetts Division of Fisheries and Wildlife is to protect and conserve fish and their habitats. Resident fish species are an important component of the river's ecology and in some cases are the basis for a sport fishery. This requested study will help protect and conserve resident fish species by ensuring project operations do not negatively impact their spawning success and spawning habitats.

Public Interest

The requestor is a resource agency.

Existing Information

To our knowledge, no information exists related to this requested study. The Massachusetts Integrated List of Waters shows the project area from the Vermont/New Hampshire state line to the Turners Falls Dam impaired due to "other flow regime alterations."

Nexus to Project

Project operations have the potential to impact fish species by influencing spawning success and spawning habitat quality and quantity. For example, water level changes due to project operations could create conditions where fish eggs are exposed to air, where spawning habitat is dewatered, and/or where fish abandon nests containing eggs.

Methodology Consistent with Accepted Practice

Common tools to evaluate water level impacts would be used, including bathymetric mapping and measurement of physical habitat characteristics such as substrate, depth and velocity. Studies should be conducted throughout the spawning season (e.g., April through August).

Common tools to evaluate fish spawning would be used, including visual observations of habitats and sampled fish (i.e., in spawning condition, coloration, gonads mature, and other external features that become developed with spawning) collected by gears such as electrofishing, seining and other net gears during defined environmental and/or time windows for spawning activity. Project operation-impacted areas should be quantified to identify and define areas subject to dewatering and mapped relative to observations of fish nests, spawning fish, and egg deposits. During identified spawning periods for the target species, suitable spawning habitats subjected to daily project operational fluctuations will be surveyed to document the type and extent of project effects on nests or spawning

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

habitat (e.g., nests of fallfish, lamprey, bass and sunfish) and observable eggs or larvae, relative to water level and other environmental conditions, including water temperature and water velocity in noted areas.

At least one year of data collection is necessary. A second year of study may be required should environmental (e.g., river discharge, air/water temperature) or operational conditions in the first year prove to be atypical during the study period (end of March through August).

Level of Effort/Cost, and Why Alternative Studies Will Not Suffice

FirstLight Power does not propose any studies to meet this need. Estimated cost for the study is moderate.

Requested Study No. 16.

Evaluate the frequency and impact of:

- 1) Emergency water control gate discharge events and:**
- 2) Bypass flume spill events, on shortnose sturgeon spawning and rearing habitat in the tailrace and downstream from Cabot Station**

Goals and Objectives

This evaluation should directly address the impact of sediment disturbance and excessive velocities on habitat in Cabot Station tailrace and downstream resulting from emergency water control gate discharge events and bypass spill events and effects of spill from the downstream fish bypass sluice on shortnose sturgeon spawning and incubation.

The goal of this study is to determine appropriate scenarios for operation of the emergency water control gates and bypass flume that will be sufficiently protective of shortnose spawning and rearing below Cabot Station from excessive water velocities and exposure to abrasive sediments dislodged and transported across spawning and rearing areas. Furthermore, avoidance or minimization of rapid fluctuations in flow is also a goal of this study applicable to the operations of the emergency water control gates and bypass flume.

The objective of the study will be to determine how often the emergency water control gates are operated to discharge large quantities of water and evaluate the impact of these events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot Station. Another objective is to understand the operation of the bypass flume that result in bypass flume spill events and evaluate the impacts of these spill events on sediment transport and bottom velocities within known shortnose sturgeon spawning and rearing habitat below Cabot station. Even when bottom velocities fall within the range optimum for shortnose sturgeon spawning, rapid fluctuations may result in sediment transport having a harmful impact on developing eggs and embryos.

Specific Objectives include:

- Emergency water control gate discharge events
 - Field verification during operation of the emergency water control gates during a range of spill and discharge conditions is necessary during years 2014 and 2015 if emergency water control gates will continue to be operated during shortnose sturgeon spawning and rearing (April 15th – June 22nd).
 - Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the emergency water control gates that will avoid or minimize negative impacts to spawning and rearing habitat.
- Bypass flume spill events
 - Field verification during bypass flume spill events under a range of spill and discharge conditions is necessary during years 2014 and 2015 if bypass flume spill events continue to be a part of future project operations and will occur during shortnose sturgeon spawning and rearing (April 15th and June 22nd).
 - Collection of sedimentation and bottom velocity data during 2014 and 2015 is necessary to verify proposed alternative operation scenarios for the bypass flume that will avoid or minimize negative impacts to spawning and rearing habitat.

Resource Management Goals

The Division seeks to understand current emergency water control gate bypass flume operations and associated impacts to determine potential operation scenarios that avoid or minimize negative effects on shortnose sturgeon spawning a rearing.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is resource agency.

Existing Information

The emergency water control gates are used to spill large amounts of water and Cabot Station also spills water from the bypass flume (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007). These large spill events created a plume of turbid turbulent flow, which caused some females to leave the area (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007). Additional spill events create a scour effect on the bottom and the scoured sediments are then pushed downstream over, or deposited on spawning and rearing shoals where an entire years class of Shortnose sturgeon eggs early life stages may be destroyed (Kynard et al. 2012, chapter 3, Kieffer and Kynard 2007). Information included in the PAD does not address operation of the emergency water control gates or bypass flume and impacts on shortnose sturgeon spawning and rearing.

Nexus to Project

The large and rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of the project (Cushman 1985, Blinn 1995, Freeman *et al.* 2001). One of the two critical shortnose sturgeon spawning and rearing areas in the Connecticut River is located within the Cabot Station tailrace and impacted by the project's discharges, including spill from the emergency water control gates and bypass flume. This section of the Connecticut River also contains habitat that supports important spawning and rearing areas for migratory fish such as American shad and American eel. Current operations of the emergency water control gates and bypass flume create flow dynamics that are not sufficiently protective of shortnose sturgeon spawning and rearing. Results of this study will be used by the Division to determine recommendations for operation of the emergency water control gates and bypass flume that will avoid or minimize sedimentation and improve bottom velocities that are sufficiently protective of shortnose sturgeon spawning and rearing.

Methodology Consistent with Accepted Practice

River hydrology modeling is commonly employed at hydroelectric projects to assess implications of project operations on the river environment. It is assumed that the planned hydrologic modeling can incorporate emergency water control gate operations and associated impacts. Thus, an additional model would not be required for this request.

Field assessment will be needed to collect sedimentation and bottom velocity data at the emergency water control gates and fish bypass sluice discharge areas to determine what operational scenarios of those structures avoid or minimize impacts to shortnose sturgeon spawning and rearing. Velocity gauges will be employed to collect data on bottom velocities associated with project operations at Cabot Station. Coordination of gauge placement for this request with the field measurements for the instream flow study should help minimize the number of necessary gauges. Field assessment of sedimentation may be collected using a variety of techniques. One potential method of collection of sedimentation data would be to set fine-mesh nets similar to shortnose sturgeon larval collection nets; these nets may show changes in the amount of dislodged substrate material that travels along the spawning site as a result of powerful releases at both the Cabot spillway and bypass flume.

Level of Effort/Cost, and Why Alternative Studies will not suffice

Field verification for this study request will likely be coordinated with other field work for related study requests. It is not expected that the required field work for this request will result in significant additional cost and effort beyond what is expected for field work related to the instream flow study request. Post-fieldwork data analysis would be a moderate cost and effort. We anticipate that the level of effort and costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., the Conowingo Project, FERC No. 405).

Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 16.
Impacts of Turners Falls Canal Drawdown on Fish Migration and Aquatic Organism Populations

Goals and Objectives

Quantitatively assess the effects of the Turners Falls Canal drawdown on diadromous fishes and other aquatic organisms known to be present in the canal during the annual drawdown.

Objectives of this study request include:

- Determine whether juvenile shad and American eel abundance in the canal increases leading up to the time of its closure, due to delays in downstream passage (e.g., is fish accumulation occurring?)
- Determine level of mortality for juvenile sea lamprey from exposure of burrow habitats;
- Conduct surveys to determine aquatic organisms (fishes, freshwater mussels, and mudpuppies) present in the canal during the drawdown, their densities, status (stranded, dead, alive), and locations (mapping to document habitat, substrate type, wetted, at complete drawdown);
- Evaluate measures to minimize aquatic organism population impacts of the canal drawdown.

Resource Management Goals

The Connecticut River Atlantic Salmon Commission developed *A Management Plan for American Shad in the Connecticut River* in 1992. Management Objectives in the plan include the following:

- Achieve and sustain an adult population of 1.5 to 2 million individuals entering the mouth of the Connecticut River annually.
- Maximize outmigrant survival for juvenile and spent adult shad.

The Atlantic States Marine Fisheries Commission Amendment 3 to the Interstate Fishery Management Plan for Shad and River Herring (American Shad Management), approved in 2010, has the stated goal of “*Protect, enhance, and restore Atlantic coast migratory stocks and critical habitat of American shad in order to achieve levels of spawning stock biomass that are sustainable, can produce a harvestable surplus, and are robust enough to withstand unforeseen threats,*” and includes the following objective:

- Maximize the number of juvenile recruits emigrating from freshwater stock complexes.

and recommendation:

- To enhance survival at dams during emigration, evaluate survival of post spawning and juvenile fish passed via each route (e.g., turbines, spillage, bypass facilities, or a combination of the three) at any given facility, and implement measures to pass fish via the route with the best survival rate.

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to diadromous fishes, the Division’s goals are:

- Minimize current and potential negative project operation effects on diadromous fishes, including juvenile shad, adult silver eels, and sea lamprey ammocetes.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures

Comments of the Massachusetts Division of Fisheries and Wildlife

pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), and the Clean Water Act (33 U.S.C. §1251 *et seq.*).

Public Interest

The requestor is a resource agency.

Existing Information

Existing information in the PAD does not provide data on the population size or survival rates of juvenile American shad, American eels, or juvenile sea lamprey located in the power canal during the de-watering process. The power canal is dewatered in early September of each year for over a one week period to perform facility maintenance, inspections, and repairs including substantial silt removal and bank repairs. Historically, the canal drawdown occurred in July, but approximately five years ago it was moved to September, where it has occurred annually since then, with the exception of 2010. The agencies were informed in a letter by FLP that the shift to September was at the request of the Independent System Operator –New England (ISO-NE) to avoid peak load months of June through August. Studies conducted by the previous operator, Northeast Utilities Service Company (NUSCO), to assess downstream clupeid survival and use (1991 and 1994 studies at Cabot Station) support the contention that juvenile shad out-migration is occurring within the current drawdown time frame. There are no data to suggest that out-migration would occur earlier than 1 August, but likely does begin in the month of August (O'Donnell and Letcher 2008). Based on these data, CRASC altered its Fish Passage Notification Letter for Downstream Passage Operations for juvenile shad and herring to require the Cabot Station downstream bypass to begin operating on 15 August in 2010 and then moved the date to 1 August in 2011

It is unknown, whether the power canal may, through potential mechanism(s) of delay due to its configuration or operation, cause out-migrating juvenile shad to accumulate in the canal. This information gap leads to concerns that migrant numbers may be elevated beyond simple extrapolations of surface area comparison in the canal to main stem habitat. In the PAD, FLP indicates that the Cabot Station forebay in the vicinity of the intake has a maximum depth of 60 feet, while the existing near-surface downstream bypass structure at the Cabot Station is designed to operate only within a depth of six feet of the surface. As a result, the downstream bypass only operates effectively for a short period during the drawdown period (timing of this is unknown). The only points of egress, once the bypass becomes unavailable, are through the turbines at Cabot as well as at Station 1, and eventually at the Keith Street gate located well upstream from the Cabot Station intakes. It is unknown what the survival rates are for these passage routes, what proportion of fish are using each route, what number may become stranded and their survival rates, and how many fish are subjected to this situation. The related Study Requests on downstream juvenile shad outmigration and American eel outmigration outline objectives that would address some of these information gaps.

There is also a paucity of information relative to the disposition of fish moving downstream in the impoundment during the canal drawdown. Once the Turners Falls Gatehouse closes its gates, all inflow passes over the dam; a situation unique to this brief one week annual time period. Survival rates for outmigrating juvenile American shad and adult American eel moving past the project during the period of spill are not known.

Lastly, there exists an information gap regarding the fate of juvenile sea-lamprey (known as ammocetes) that reside in the soft substrate materials located in much of the lower or downstream end of the canal (personal communication, Boyd Kynard). In previous drawdowns, thousands to tens of thousands of dessicated ammocetes have been observed (Matt O'Donnell, personal communication, USGS Conte Lab). However, the distribution and abundance of ammocetes in the canal as well as mortality rates for ammocetes during the drawdown period has not been quantitatively determined.

Nexus to Project

Previous studies at Cabot Station have documented that juvenile American shad and American eel migrate through the project area during the canal drawdown period. During normal operations (where canal water level elevations are stable), downstream migrants are able to utilize the Cabot bypass facility; however, as the canal water level is drawn down, the bypass is no longer available, and the only routes of egress are through the turbines at Cabot Station and Station 1, unless the Cabot Station spill gates are utilized (the spill gates have a canal depth limitation of approximately 16 feet). Turbine entrainment at hydropower projects has been shown to cause injury and mortality to fishes.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The annual canal drawdown was formerly conducted in July. In response to ISO-NE's request that FL conduct the drawdown outside of the June through August period, FL moved the drawdown to a period of time when diadromous fishes are known to be moving through the project area.

Once the canal has been drawn down, isolated shallow pools are left standing until the canal is refilled. During this period, fish (including lamprey ammocetes), amphibians, and benthic invertebrates are prone to dessication, predation or other sources of mortality or impact.

Methodology Consistent with Accepted Practice

The methods presented here are consistent with the study requests addressing downstream juvenile American shad passage and downstream American eel passage, with an emphasis on addressing survival and movement immediately prior to and during the canal draw down. Hydroacoustic monitoring immediately upstream of the Turners Falls Gatehouse, as well as upstream of opened dam gates for spill, will provide data on the timing, frequency and magnitude of natural wild juvenile shad movement into these areas, particularly the power canal. The abundance of juvenile shad moving into the canal can be derived and compared with similar data obtained with hydroacoustic equipment monitoring upstream of the Cabot Station intake and bypass, for comparisons. Juvenile shad will be PIT tagged, released, and monitored in the canal, for movements, timing and location including Station 1 canal and forebay. PIT tagged fish will be detected at the Cabot Bypass Sluice sampler. Juvenile fish should be specifically targeted for release immediately prior to drawdown to assess survival and movement in and through the canal. Surveys of sea lamprey ammocetes should be conducted by a stratified sampling design based upon substrate.

Lamprey density surveys, immediately after drawdown and in a subsequent later survey, may derive rates of change in observed densities and their status (live, moribund, dead); appropriate methods would need to be discussed. Surveys of remaining ponded water should be conducted immediately following drawdown and at later intervals (mid-week and end of week) to compare species occurrence and densities (relative abundance) which will be used to develop catch-curve analyses that can inform rates of mortality to the observed populations.

Assessments of freshwater mussels should also be conducted to quantify drawdown impacts. As with lamprey, the assessment can be based on sampling identified habitats in a stratified, random design, over the three time periods noted (initial drawdown, mid week, and end of week), tracking changes in densities and status of observed individuals among areas. Sub-sampling, with sufficient repeated measures to determine variability and acceptable level of precision of data will inform the required sampling intensity that will be needed. This sampling intensity will be determined as the study occurs and may vary among identified species. Comparisons among the three time periods for measures of density and status will inform the evaluation of project effects for juvenile shad, sea lamprey ammocetes, freshwater mussels and mudpuppies

The canal drawdown mitigation assessment involves evaluating alternative drawdown protocols to minimize impacts to resident and migratory fish, mussels and amphibians inhabiting the canal. Alternatives should include: (1) moving the drawdown to a time of year outside of migration seasons; (2) keeping or moving the timing of the drawdown, but utilize technologies to keep the majority of the canal wetted during the drawdown (e.g., portadams in the forebay immediately upstream of the trashracks and at other canal intakes in need of maintenance); and (3) in combination with alternative #2, assess whether other existing infrastructure within the forebay could be used to pass fish safely out of the canal (e.g., low level outlets, deep gates, side spillway boards, etc.). The assessment should compare the merits and drawbacks of each alternative and provide an order of magnitude cost estimate for implementation.

Level of Effort/Cost, and Why Alternative Studies will not suffice

This Study Request has many elements that overlap directly with a larger scale downstream juvenile American shad passage and downstream American eel passage study requests. With equipment costs principally covered in those requests, many components of what has already been proposed will be used in this study. However this request does include some specific elements not specified in the other two larger requests. The study cost and effort are expected to be low to moderate. Some additional radio tags and balloon tags with additive days of field work to accurately assess impacts specific to the drawdown period will be required. Surveys for identified aquatic organisms will take several days during the drawdown period as well.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The canal drawdown mitigation assessment should require a low to moderate level of effort and cost. One staff person would evaluate alternative drawdown protocols. This should take less than one week to complete.

The applicant did not propose any studies to meet this need in the PAD.

Requested Study No. 18.
Climate Change as it Relates to Continued Operation of the Northfield Mountain Pumped Storage, and Turners Falls Projects

Goals and Objectives

This study should relate to the cumulative impacts of the five Connecticut River projects being relicensed at this time. The goal of this study is to determine how climate change relates to the continued operation of the Vernon, Bellows Falls, Wilder, Northfield Mountain Pumped Storage, and Turners Falls projects.

The objectives of this study are:

1. Quantify the amount of thermal loading contributed by each respective impoundment (including the NMPS upper reservoir).
2. Using climate change prediction models, calculate how much warmer the project impoundments are projected to get in the next 30-50 years.
3. Model the effect of various project modifications on river temperature under current conditions and climate change predictions (e.g., converting to run-of-river, deep-water releases, dam removal, large-scale riparian revegetation, etc.).
4. Using climate change prediction models, determine if the projects actually provide an environmental benefit with respect to mitigating against climate change impacts (vis a vis warming of air and water temperatures) by producing low greenhouse gas emitting energy. The Northfield Mountain Pump Storage assessment must be based on net energy production (i.e., NMPS generates 1,143,038 MWh annually, but consumes 1,567,506 in its pumping operations; for a net consumption of 424,468 MWh annually).
5. Determine how climate change predictions will impact management of high flow events at the three projects and evaluate if changes to dam structures would mitigate adverse impacts of the existing flood management protocols.

Resource Management Goals

The Division seeks the accomplishment of a number of resource goals and objectives through the relicensing process for the Project. General goals include the following:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and help meet regional fish and wildlife objectives for the basin.
- Conserve, protect, and enhance the habitats for fish, wildlife, and plants that continue to be affected by the Project.

Specific to climate change, the Division's goals are:

- Minimize current and potential negative project operation effects that could hinder management goals and objectives.
- Minimize deep headpond drawdowns associated with the loss of stanchion logs during high flow events, which are predicted to increase due to climate change.
- Minimize project-related sources of thermal increases to Connecticut River waters to mitigate against predicted climate change impacts.

In September 2011 The MA Executive Office of Energy and Environmental Affairs published the *Massachusetts Climate Change Adaptation Report*. Strategies identified in this report include measures that preserve, protect, and restore natural habitats and the hydrology of watersheds. These strategies strive to integrate the protection of rivers, streams, lakes, riparian areas, floodplains, and wetlands with comprehensive land-use, watershed, and floodplain/buffer management, and targeted land acquisition. Strategies include:

- Land Protection
- Develop streamflow criteria and regulations to encourage re-establishment of natural flow regimes in rivers and streams.
- Identify vulnerable river reaches, establish and protect belt-width-based river corridors, restore floodplains, and increase use of bioengineering techniques for bank stabilization.
- Seek to reconnect high quality habitats by removing in-stream barriers and re-establishing in-stream flows.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

- Identify and implement strategies for early detection, rapid response, and prevention of invasive exotic plants and animals that out-compete native species and gradually reduce the diversity of species composition.
- Through geomorphic assessment, identify vulnerable river reaches and monitor rivers for disconnection from floodplains.

Our study requests are intended to facilitate the collection of information necessary to conduct effects analyses and to develop reasonable and prudent conservation measures, and protection, mitigation, and enhancement measures pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. §1531 *et seq.*), the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), and the Federal Power Act (16 U.S.C. §791a, *et seq.*).

Public Interest

The requester is a resource agency.

Existing Information

The PADs contains no information relative to climate change and how climate change predictions may impact future operation of the hydroelectric plants, nor of how the projects either mitigate for or exacerbate predicted climate change impacts to freshwater ecosystems.

TransCanada’s PADs provide a summary of water quality data collected in 2012. Table 1 below is a synthesis of the temperature data collected by TransCanada. It should be noted that the upper and mid-impoundment stations at each project represent the average of temperature readings taken over the entire water column, while the continuous loggers (Lower Cont. and TR) were located near the water surface. These data indicate that from the upstream end of the Wilder headpond to the Vernon tailrace, water temperature increased approximately 6°C.

Table 1. Median water temperature at monitoring stations located within the impoundments and tailraces of the three hydropower projects.

Project	Median Water Temperature °C			
	Upper Imp.	Mid-Imp.	Lower Cont.	TR
Wilder	20.86	21.83	24.08	23.59
BF	22.43	23.67	24.86	24.38
Vernon	23.81	24.49	26.73	26.35

Relative to existing flood management protocols at each station, TransCanada’s PADs identify that all three dams utilize stanchion bays (two at Vernon, three at Bellows Falls, and four at Wilder). When inflows to each dam reach certain levels, the stanchion bays are removed, and cannot be replaced until inflows subside. The depth of these bays and the flows they are removed at are outlined in Table 2, below.

Table 2. Summary of pertinent stanchion bay information for the Vernon, Bellows Falls, and Wilder projects.

Project	Stanchion Height (feet)	Flow Triggering Complete Stanchion Removal
Wilder	17	145,000 cfs
BF	13	50,000 cfs
Vernon	10	105,000 cfs

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

The PADs provide no information on the history of stanchion removal at any of the projects (frequency, duration, timing), nor a discussion of how predicted climate change might alter management of the stanchion bays in the future (with respect to the frequency and seasonality of occurrence). There also is no discussion of potential impacts to headpond resources that occurs as a result of stanchion bay removal. These information gaps need to be filled so resource agencies can assess the relative and cumulative impact of project operations with respect to the Division's management goals and objectives, including those identified in the Massachusetts Climate Change Adaptation Report.

Data provided by the National Oceanic and Atmospheric Administration, Climate Data Center, illustrates long-term increasing air temperatures in the Northeast (Figure 1). Long-term, monthly mean water temperature data for the Vernon Dam impoundment, monitored by Vermont Yankee, has shown significant differences over time (ANOVA analyses, $P < 0.05$) that when plotted and further analyzed by linear regression, show a significant increasing trend for the period 1974 – 2011 for the months of January, September, and October (Figure 2). These analyses were performed with data from Vermont Yankee, analyzed by the Massachusetts Department of Environmental Protection.

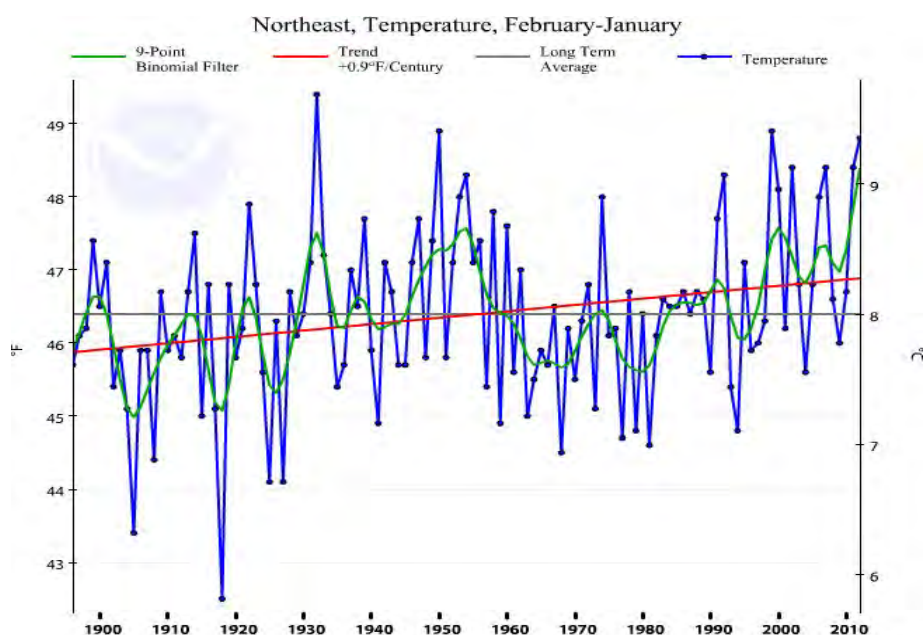

Figure 1. NOAA National Climate Data Center, Northeast 12-month average temperature for the period 1896 through 2012 (October).

Comments of the Massachusetts Division of Fisheries and Wildlife
 Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

VY Station 7 - September Mean Monthly Temperature

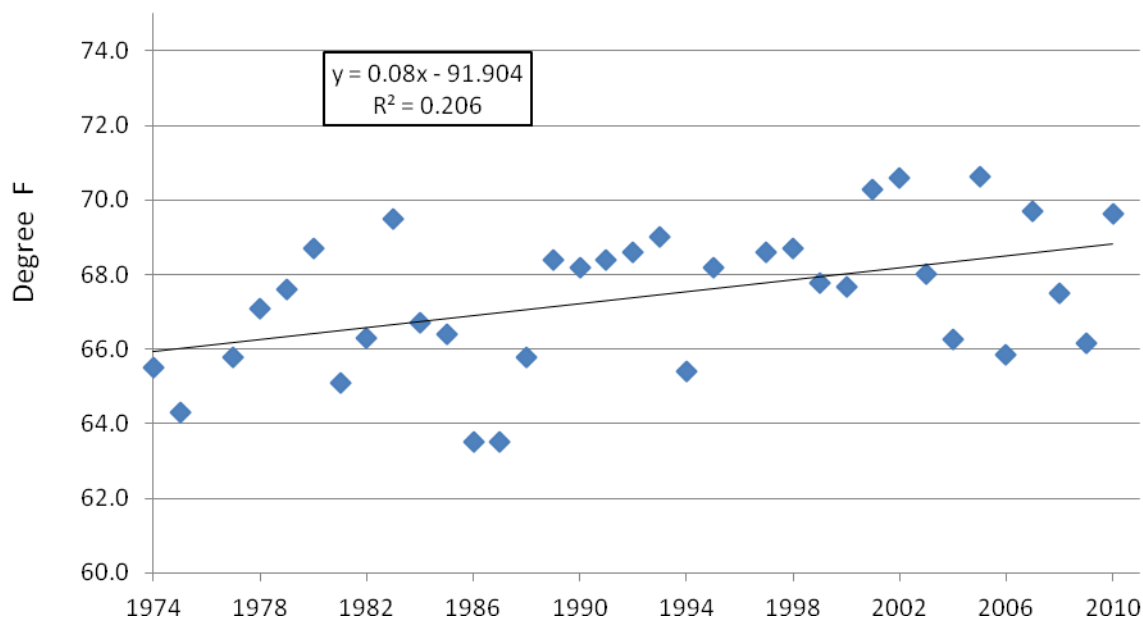

Figure 2. A plot of September’s mean temperatures for Vermont Yankees’ Station 7 (excludes outlier 1996 data point) for the period 1974 through 2011.

The PAD for Turners Falls and Northfield Mountain Pump Storage projects provides a summary of existing water quality data compiled by FirstLight, including water temperature data obtained from the U.S. Fish and Wildlife Service. The PAD also notes a 1991 study by the former licensee that modeled thermal effects of pumping to the upper reservoir. That model reported a maximum temperature difference attributable to NMPS operation of 0.21°C in the Turners Falls reach of the Connecticut River in low flow (4,000 CFS) simulation.

Nexus to Project

The four mainstem projects have very long impoundments capable of storing large volumes of water (Table 3, below). These impoundments effectively have converted large portions of the Connecticut River into a series of in-river “lakes.” Because water velocities slow in these impounded sections of river, it allows for increased thermal loading and resultant higher water surface temperatures than in free-flowing sections of river.

Table 3. Relevant characteristics of the reservoirs behind the Wilder, Bellows Falls, Vernon, Turners Falls dams and NMPS.

Project	Headpond Length (miles)	Gross Storage Volume (acre-ft.)	Average Depth (ft.)	Surface Area (acres)	Flushing Rate (days)
Wilder	45	34,350	11	3,100	3
BF	26	26,900	10	2,804	<2
Vernon	26	40,000	16	2,550	2
Turners	20	21,500		2,110	
NMPS	n.a.	17,,050		246	n.a.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Depending on where the hydropower intakes withdraw water, these warmer surface waters may be discharged downstream, raising the temperature of those waters as well (the data in Table 1 above suggest that the projects do draw water from the upper levels of the reservoirs). This effect may be felt for miles downstream. If there are a series of impoundments (like on the Connecticut River), the cumulative impact is an overall warming of the river. Even small run-of-river dams have been shown to elevate downstream water temperature (Lessard and Hayes 2003; Saila et al. 2005). The most recent climate change prediction models specific to the northeast forecast warmer air temperatures, more frequent high precipitation events, more heat waves, and an increase in the incidence of short term droughts (Karl et al. 2009).

Resource concerns related to this project effect include the potential impacts to populations (reductions in abundance, structure, condition) or loss of species not tolerant of increases in temperature and other effects related to physiology such as energetic costs with warmer temperatures (Leggett 2004). As one example, American shad restoration target numbers for fish passage at mainstem dams into upstream historic habitat could be negatively impacted from artificially increased water temperatures. Water temperature has been identified as a factor in the timing (i.e., duration) of this species migration, as well as its role in gonad development and spawning (Glebe and Leggett 1981; Leggett 2004). These factors can be logical reasoned to potentially result in accelerated rates of energy reserve use and a reduced migration window, possibly reducing the ability of fish to reach up-river habitats and further reducing the ability to survive downstream outmigration.

With respect to project operations during high flow events, all TransCanada projects have stanchion bays that are used to manage water during high flow events. Each time these stanchion bays are removed, the headponds are lowered substantially (from 10 to 17 feet, depending on the project) and must remain lowered until inflows subside. Depending on the timing and duration of these deep drawdowns, headpond resources could be negatively impacted.

All of the dams also contain other mechanisms for managing flows, such as tainter gates, sluice gates, roller gates, skimmer gates and hydraulic flood gates. All of these gates have an advantage over stanchion bays in that they do not require flows to subside significantly before they can be closed to return impoundment levels back to normal. One climate change prediction for the northeast is that we will see more frequent high precipitation events which will result in high flow conditions on rivers. Therefore, it is likely that the stanchion bay removal protocol will have to be employed more frequently in the future.

Methodology Consistent with Accepted Practice

- In order to quantify the amount of thermal loading contributed by each respective impoundment, detailed bathymetry will need to be collected. This bathymetry, combined with storage volume, tributary hydrology, and project operations, should be used to calculate the thermal loading of each headpond. The individual and cumulative increase in surface water temperature due to the impoundments should then be used to predict future warming based on climate change models.
- Analyze different mitigation strategies to understand which have the greatest benefit in terms of building resilience against the impacts of climate change on water temperature. Potential scenarios to analyze include converting the projects to run-of-river, implementing deep-water releases, removing one or more dams, conducting large-scale riparian revegetation, etc.).
- Input to climate change models the amount of GHG emissions that would be generated if fossil fuel plants were producing the equivalent amount of net energy as the five hydropower projects to determine the impact on air and surface water temperatures.
- Climate change prediction model output should be assessed to determine if the frequency and timing of high flow events is likely to change in the future. If high flow events that necessitate initiating the stanchion bay removal protocol are predicted to increase in frequency and/or shift in timing, the applicant should evaluate structural and/or operational alternatives that would mitigate adverse impacts of the existing flood management protocols.

Level of Effort/Cost, and Why Alternative Studies will not suffice

The level of cost and effort for the thermal loading analysis would be low to moderate. Collecting bathymetry in the three TransCanada headponds would take two staff less than one week to collect (it took the Kansas Biological Survey two days to collect bathymetry at a 3,500 acre lake; Jakubauskas et al. 2011). Bathymetry for the Turners

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Falls pool and NMPS upper reservoir already exist. The remaining work would be desk-based; loading relevant information into an appropriate thermal loading model to compute the estimated thermal loading of each headpond and then comparing this information to surface water data from climate change prediction models.

The high flow flood protocol study is a desktop analysis that should require low cost and effort. Climate change models already exist and that output would be downloaded and analyzed. The remaining analysis requires a review of alternative means of managing flows without the use of stanchion bays.

The applicants did not propose any studies to meet this need in the PAD.

Requested Study No. 19.
Integrate Modeled River Flows and Water Levels with Habitat Assessment for State-listed Riparian Invertebrate Species

Goals and Objectives

The goal of this study is to develop a river flow model(s) that evaluates hydrologic changes in the Connecticut River caused by the physical presence and operation of the Turners Falls Dam (TFD) Hydroelectric Project, the Northfield Mountain Pumped Storage Project, the Vernon Hydroelectric Project (P-1855), the Holyoke Dam, and river flows. The model should specifically assess the influence of existing and proposed Project operations on water levels at both known populations and potential habitats for state-listed invertebrate species - including the Cobblestone Tiger Beetle (*Cicindela marginipennis*), state-listed as “Endangered,” and the Puritan Tiger Beetle (*Cicindela puritana*), state-listed as “Endangered” and federally-listed as “Threatened” – and assess how Project operations may be modified to conserve and enhance existing populations and potential habitats.

The specific objectives of this study are to:

- A. Conduct quantitative modeling of the hydrologic influences and interactions that exist between water surface elevations within the TFD Impoundment, discharges from the TFD (and its associated generating facilities), and both up- and downstream hydroelectric projects. Data inputs to and outputs from the model(s) should include:
 - a. Withdrawals from and discharges to the TFD Impoundment from the Northfield Mountain Pumped Storage Project.
 - b. Discharges into the TFD Impoundment from the Vernon Hydroelectric Project and other sources.
 - c. Existing and potential water level fluctuation restrictions (maximum and minimum pond levels) of the TFD Impoundment and downstream flows.
 - d. Existing and potential discharges from the TFD and its associated generating facilities and spill flows.
- B. Assess how water level fluctuations within the TFD Impoundment affect potential habitat for state-listed invertebrate species, and assess what changes would be needed to Project operations to stabilize water levels and maintain/enhance said habitats.
- C. Assess how Project operations affect potential habitat for state-listed invertebrate species downstream from the TFD - with an emphasis on the influence of water levels on known habitat for the state-listed Cobblestone Tiger Beetle - and assess what changes would be needed to Project operations to stabilize water levels and maintain/enhance said habitats.
- D. Assess how Project operations affect water levels within the Holyoke Dam Impoundment - with emphasis on the influence of water levels on known habitat for the state- and federally-listed Puritan Tiger Beetle - and assess what changes would be needed to Project operations to stabilize water levels at Rainbow Beach.

Relevant Resource Management Goals

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Our study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, protection, mitigation and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA.

Public Interest

The requestor is a fish and wildlife resource agency, with regulatory authority under the MESA and the WPA.

Background and Existing Information

The PAD does not indicate how Project operations have or will alter hydrology in the Connecticut River from below the Vernon Hydroelectric Project downstream to the Holyoke Dam, or how operations have or may affect known populations and potential habitats for state-listed invertebrate species, including the Puritan and Cobblestone Tiger Beetles. However, the daily peaking mode of current Project operations are widely believed to negatively affect known populations; it is also likely that Project operations reduce the extent and quality of potential habitat for these species within the Connecticut River more broadly. However, the Division is not currently aware of any studies that have evaluated the relationship between Project operations, river hydrology, known populations, and potentially suitable habitat.

Puritan Tiger Beetle is among the most imperiled species in the United States, and populations of both the Puritan and Cobblestone Tiger Beetles are severely limited in Massachusetts. The only known population of each species is found along the Connecticut River, with Puritan Tiger Beetle known from a single site in Northampton, MA and Cobblestone Tiger Beetle known from a single site in Montague, MA, first observed in 2000. Annual reports from the monitoring of Puritan Tiger Beetle adults and larvae have documented the negative effects of flooding on the known Massachusetts population (Davis 2002-2012, unpublished).

Nexus to Project

The TFD is currently operated with a seasonally-varying minimum bypass flow (400 cfs from 5/1 through 7/15, then 120 cfs through the winter until river temperature rises to $\geq 7^{\circ}\text{C}$) and year-round minimum flows below the TFD of 1,433 cfs. The Project operates on a daily peaking mode, often with large, rapid, downstream daily flow fluctuations between this minimum and Project capacity (15,928 cfs) as well as fluctuations in headpond elevation (175' to 186' MSL). Large, rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota both up- and downstream of such facilities. Further, existing and potential Project operations are influenced by operations at upstream peaking projects, including (primarily) the Vernon Hydroelectric Project and the Northfield Mountain Pumped Storage Project. Indeed, potential changes to the operations of any project could affect the ability to achieve desired operational changes of other projects. Results of river flow analyses should be combined with field assessments of potentially suitable habitats to determine appropriate flow recommendations that will protect and/or enhance known populations as well as potential habitats for state-listed invertebrate species.

Proposed Methodology

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess the effects of project operations on the river environment. Field assessments are also common in developing operational regimes that will reduce impacts or enhance habitat conditions up- and downstream of hydroelectric projects. Field assessments should involve collecting flood depth, timing, duration, as well as frequency and changes to substrate characteristics along the mainstem of the Connecticut River sufficient to permit assessment of how the quality, extent, and location of existing and potentially suitable habitat changes over a range of flows. The measurements should be taken over a range of test flows, between the existing minimum flow and maximum project generation flows. This information should be synthesized to quantify habitat suitability for each species under each test flow.

Level of Effort and Cost

Level of effort and cost of model development are expected to be moderate, but in order to be valuable in developing revised license conditions, the model(s) should be run under a suite of various scenarios throughout the relicensing process to assess the implications of changes to the operations of any project on other projects and target natural resources. The modeling exercise will also require coordination and cooperation between FirstLight and the upstream licensee to assure that model inputs and outputs can be accurately related. Field work for habitat

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

assessment studies can be reasonably extensive, but will depend on further consultation with the Division regarding study methodology and on-site decisions for the locations and the number of data replicates. Post-fieldwork data analysis would be of moderate cost and effort.

We would anticipate that the expected level of effort and anticipated costs will be comparable to that experienced on similar FERC relicensing projects of this size (e.g., Conowingo, FERC No. 405).

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 20.
Habitat Assessment, Surveys, and Modeling of Suitable Habitat for State-listed Mussel Species in the Connecticut River

Goals and Objectives

The goal of this study is to conduct an instream flow habitat study and field surveys to assess the impacts of existing and proposed discharges from the Turners Falls Dam (TFD) Hydroelectric Project on suitable habitat and existing populations of state-listed mussel species downstream of the TFD, if any, of the Yellow Lampmussel (*Lampsilis cariosa*), state-listed as “Endangered,” and the Eastern Pondmussel, state-listed as “Special Concern.” In addition, the results of the study can be used to assess how Project operations may be modified to conserve and enhance these populations/habitats.

The specific objectives of this study are to:

- A. Delineate, through field survey, populations of state-listed mussels downstream of Cabot Station and determine their distribution, abundance, and age-distribution within and between populations.
- B. Delineate, through field survey, parameters of habitat suitability for each state-listed mussel species.
- C. Evaluate the effects of existing and potential flow regimes on suitable habitats for the state-listed Yellow Lampmussel and Eastern Pondmussel, and determine an appropriate flow regime that will protect and enhance existing populations and suitable habitats in the Connecticut River.

Relevant Resource Management Goals

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations

Our study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, protection, mitigation and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA. Specific to state-listed mussels, the Divisions goals are to:

- Protect, enhance, or restore diverse high quality aquatic habitats for state-listed mussel species in the Connecticut River watershed and mitigate for any loss or degradation of these habitats.
- Minimize current and potentially negative effects of Project operations on state-listed mussels and their habitats.

Public Interest

The requestor is a fish and wildlife resource agency, with regulatory authority under the MESA and the WPA.

Background and Existing Information

It has been well documented that the damming of rivers can have detrimental impacts on mussel communities inhabiting areas both upstream and downstream of dams (Watters 1999, Layzer et. al. 1993, Moog 1993). The PAD provides a list of plant and wildlife species whose native ranges overlap with the Project area. In 2011, FirstLight facilitated surveys for state- and federally-listed mussel species within the 19.5-mile TFD Impoundment, the 3.5-

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

mile long bypass reach of the TFD, and the facility's 2.2-mile long power canal by Biodrawversity, LLC. No state- or federally-listed mussel species were found by these surveys. This survey was semi-quantitative, the main goal being to assess the distribution, abundance, demographics, and habitat of state- and federally-listed mussels in the 2011 study area. However, the study did not assess all suitable habitats and flow conditions or perform mussel surveys in the free-flowing reaches of the Connecticut River downstream of Cabot Station, in which populations of Yellow Lampmussel and Eastern Pondmussel have been documented and which are potentially impacted by existing and proposed Project operations. Studies to date have also not assessed how existing and proposed Project flows affect glochidial settlement of state-listed freshwater mussel species.

The range of the Yellow Lampmussel in New England is limited to four major watersheds, three of which occur in Maine and the fourth in the Connecticut River (Massachusetts and Connecticut) (Nedeau et al. 2000, Nedeau 2008). In Massachusetts, extant populations are limited to the mainstem of the Connecticut River south of the TFD, although historic records exist from reaches in Northfield (Nedeau 2008). Populations of the Eastern Pondmussel are known from the mainstem of the Connecticut River and some low-gradient tributaries.

FirstLight is required to release a minimum of 1,433 cfs into the Connecticut River below the TFD; however, the Project currently generates power in a peaking mode, resulting in significant within-day flow fluctuations between the minimum release and project capacity on an hourly or daily basis. These large and rapid changes in water elevations and flow dynamics, out of synch with expected seasonal variation, may cause adverse effects to state-listed mussels, their habitats, and their long-term viability in the Connecticut River. The Division is not aware of any studies that have evaluated these effects. Finally, information included in the PAD does not provide a detailed description of how the selected minimum flow was established, or how minimum flow relates to flows necessary for the conservation and protection of rare species.

Nexus to Project

The Project currently operates with minimum flow releases and flow regimes that do not appear to have been based on biological criteria or field study and do not mimic natural fluctuations. The timing, rate, and magnitude of releases from the TFD may have direct, adverse effects on rare mussel populations and their habitats, although the degree and character of these effects is unknown. However, before an evaluation of effects can be made a better understanding of the distribution and abundance of state-listed mussel species and their habitats is required. Therefore, in order to fill this important information gap, field surveys to establish baseline population information and suitable monitoring sites is needed. Additionally, an empirical study is needed to provide information on the relationship between the proposed mode(s) of operation and rare mussel species and their habitats in the Connecticut River downstream of Cabot Station. Results will be used to assess proposed flow regimes on existing populations (if any) and potentially suitable state-listed mussel habitat, and to determine appropriate recommendations that will protect and/or enhance state-listed mussels and their habitats.

Proposed Methodology

- A. *Habitat assessments* should be conducted during suitable water visibility and depths to afford a clear view of the river bottom between 1 June and 25 September (similar to those outlined within Biodrawversity and LBG 2012). This field work and analysis was performed on the mussel community inhabiting the lower Osage River in Missouri as part of the relicensing process of the Osage Hydroelectric Project (FERC No. 459) (ESI 2003). Surveys should provide systematic and sufficient coverage of potential habitats downstream of Cabot Station to detect occupied and unoccupied patches of suitable habitat.

Habitat should be classified regarding occupancy by state-listed mussels. Methods for the habitat assessment portion of the study should include the use of snorkel, view bucket, and scuba, as necessary, based on water depth and clarity; shoreline-based surveys are not suitable alternatives. Occupied habitat patches will be utilized as a minimum habitat condition benchmark and data collection will include macro-scale (e.g., stream gradient, distance from Cabot Station, reach habitat mapping) and micro-scale features (e.g., depth profile, velocity profile, stability of patch, substrate, temperature, aquatic vegetation and other key features). Using these measured parameters, the habitat assessment should then locate and map patches of suitable but currently unoccupied habitat, if present. The requested habitat assessment will provide habitat descriptions and mapping to adequately describe the relative amount, distribution, and quality of suitable habitat for the Yellow Lampmussel and Eastern Pondmussel in Project-affected portions of the

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Connecticut River that were not surveyed as part of the 2011 study referenced above. The Division will work with FirstLight to develop and refine a habitat assessment protocol.

- B. *Mussel Surveys.* Simultaneous with the habitat assessment, state-listed mussels will be surveyed and population parameters measured and quantified. Surveys, in conformance with Massachusetts protocols for state-listed mussel species, include:
- 1) Use SCUBA in depths over 3 feet and snorkeling in depths less than 3 feet. Mucket buckets and hand surveys may be used in very shallow or turbid waters.
 - 2) Conduct subsurface exploration in ten percent (10%) of the survey area if state-listed mussels are encountered, and/or in areas where juveniles are encountered or juvenile habitat exists (e.g., depositional areas behind rocks, along streambanks, sandbars, etc.) (Yeager et al. 1994). Substrate sediments shall be excavated using 0.25m² quadrats to a depth of 10cm and sieved through a mesh screen with openings of 4-6mm to detect juvenile mussels.
 - 3) Count and identify all state-listed mussels to species.
 - 4) Collect all standard morphometric (e.g., species, size, shell injury/erosion etc.) and site data (location, extent, elevation, and age class structure). Length (millimeters) of the first 100 state-listed mussel individuals per species should be recorded to help assess recruitment length of all state-listed specimens less than 40mm. The first 50 specimens of all common species should be counted and identified; overall common species abundance (e.g., abundant, scattered, infrequent) should be estimated.
 - 5) Use the Catch per Unit Effort (CPUE) method to qualitatively assess mussel species abundance. Estimate density at each site using number of mussels found per species per square meter of survey area.
 - 6) Collect photographs of representatives for each state-listed species per site to document and confirm identity; photos should show a lateral view. If underwater cameras are available, photos of mussels while siphoning can help confirm identification.
 - 7) Collect a representative sample of spent shells (for each species) that shall be forwarded to the Division for documentation and identification purposes.
 - 8) Return any mussels removed from the substrate to the same area and carefully re-bed into the sediment in their original orientation; anteriorly into the substrate, posterior end up.

The Division will work with FirstLight to develop and refine the survey protocols outlined above. The Division must pre-approve the candidate mussel biologist who can demonstrate adequate field experience. The ability to locate and identify state-listed freshwater mussel species and their habitat(s) is required for an adequate freshwater mussel habitat assessment, and the Division may reject assessments that are not conducted by qualified individuals. The mussel biologist is required to obtain a Scientific Collection Permit from the Division, pursuant to 321 CMR 10.04, to handle dead or live state-listed mussels. If federally-listed mussel species are present, the mussel biologist may also need a permit from the USFWS (e.g., to collect vouchers).

- C. An *instream flow habitat study* should be conducted in order to collect wetted perimeter, point-velocities, and substrate data along transects located in reaches of the Connecticut River downstream of Cabot Station. The data collected by the habitat assessment portion of the study will allow for application of the instream flow habitat model to the assessment of both occupied and unoccupied patches of suitable habitat. Flow measurements should be taken in each transect and at a subset of occupied and unoccupied habitat patches over a range of test flows. Additionally, flow conditions should be evaluated to determine potential effects of current and proposed Project operations on glochidial settlement into suitable patches, using an assumed range of sizes for larval mussels. At a subset of occupied patches, an assessment of flow-effects on mussel behavior should also be conducted. The requested *instream flow habitat study* will provide habitat descriptions and mapping to adequately describe the flow conditions, relative amount, distribution, and quality of suitable habitat for the Yellow Lampmussel and Eastern Pondmussel within suitable habitat at each test flow. The types of data collected should be sufficient to permit assessment of how quality, quantity, and location of habitat changes over a range of flows between existing minimum flow, peak

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

flows, and maximum project generation flows. Similar methods are being employed to evaluate persistence of Dwarf Wedgemussel habitat on the Delaware (Maloney et. al. 2012) and Susquehanna (T. Moburg, The Nature Conservancy, personal communication) rivers, although these studies did not include the requested patch-level velocity analysis.

Level of Effort and Cost

Field work for instream flow studies may be reasonably extensive, but will depend on consultation between the applicant and the Division on study methodology and on-site decisions regarding locations for data collection and the number of collection locations. Additionally, there may be potential to combine assessment of habitat with broader in-stream flow habitat assessments requested for other target species, which would reduce costs associated with the habitat assessment component of the study. Post-fieldwork data analysis would be a moderate cost and effort. The methods proposed by the Division are widely accepted methods to assess habitat and conduct mussel surveys, and surveys of this nature are comparable to other FERC projects where state-listed mussels have been investigated.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 21.
Fish Assemblage Assessment and Glochidia Surveys in the Connecticut River

Goals and Objectives

The goal of this study is to determine the occurrence, distribution, and relative abundance of fish species in the Connecticut River up- and downstream of the Turners Falls Dam (TFD) Hydroelectric Project, including state-listed fish species as well as host fish species of the Dwarf Wedgemussel (*Alasmodonta heterodon*), federally- and state-listed as “Endangered,” the Yellow Lampmussel (*Lampsilis cariosa*), state-listed as “Endangered,” and the Eastern Pondmussel (*Ligumia nasuta*), state-listed as “Special Concern.” The study should also assess the occurrence and abundance of mussel larvae on resident host fish.

The specific objectives of this study are to:

- A. Document fish species occurrence, distribution and abundance within the Project-affected area along spatial and temporal gradients.
- B. Compare study results to historical records of fish species occurrence in the Project-affected.
- C. Assess the occurrence and abundance of state-listed freshwater mussel larvae (glochidia) on host fish species.

Relevant Resource Management Goals

The conservation and protection of species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations

Our study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, protection, mitigation and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA. Specific to state-listed fish and mussel species, the Divisions goals are to:

- Protect, enhance, or restore diverse high quality aquatic habitats in the Connecticut River watershed and mitigate for the loss or degradation of these habitats.
- Minimize current and potentially negative effects of Project operations on state-listed species and their habitats.

Determining species occurrence, distribution, and abundance of fish species more generally will better clarify what species occur in the project area both spatially and temporally relative to habitats which may be affected by Project operations. This information will better inform results from other study requests that will be examining the effects of Project operation on various aquatic habitats, water quality and other related concerns. This information will be used to make recommendations and enable full consideration for all species, including those that might not otherwise be known to occur in the Project-affected area and impacts that may affect their population status through direct or indirect effects of Project operations.

Public Interest

The requestor is a fish and wildlife resource agency, with regulatory authority under the MESA and the WPA.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Background and Existing Information

The PAD identifies a total of twenty-two fish species in the Project area, but omits any reference to the presence or absence of the tessellated darter. The PAD does note that resident fish surveys were conducted by the Commonwealth of Massachusetts in the early- to mid-1970s, and the Division is aware of a limited sampling effort by Midwest Biodiversity Institute (contracted by the U.S. Environmental Protection Agency) conducted in 2008 (Yoder et al., 2009), which represents the most relevant and recent study related to Project-affected areas. While some sampling was conducted in the Project areas during the course of the 2008 survey, it did not have the same goals and objectives as those outlined above. Although species presence was documented by this study, it did not assess the structure, distribution and abundance of species within the Project-affected areas nor estimate change in these parameters over time. The design of the study, limitations in geographic/habitat type coverage both spatially and temporally, and the use of a single gear type limits the use of this study, which may not fully represent species occurrence in Project-affected areas. It follows that since information is limited regarding the composition of fish communities and their use of habitats in the Project-affected areas, the impacts of current and proposed Project operations on fish species are also unknown. Because FirstLight has not proposed any studies specifically addressing the goals and objectives outlined above, we request a thorough and comprehensive assessment of fish assemblages in the Project areas.

As referenced in the PAD, two state-listed fish species are known to occur in the Connecticut River, including the Eastern Silvery Minnow (*Hybognathus regius*) and Burbot (*Lota lota*), both of which are state-listed as “Special Concern.” Currently, there are only two known populations of the Eastern Silvery Minnow in Massachusetts, both located in the Connecticut River. Eastern Silvery Minnow use aquatic vegetation as habitat, and therefore, are sensitive to flow alterations, erosion, sedimentation, and other factors that may reduce the quality and quantity of their habitat. Burbot are also rare in Massachusetts, with only a few individuals having been collected in the Connecticut River watershed, and, historically (records >25 years old), in the Housatonic River watershed. However, like many small bodied fishes, neither of these species are effectively sampled through boat-based electroshocking. Therefore, a fish assemblage study should be designed to ensure that small bodied fishes are adequately sampled.

Further, seven percent of unionid species are listed as possibly extinct in North America (Strayer et al. 2004, Williams et al. 1993). Watters (1996) found that 30-60% of all native mussels were negatively impacted by damming of rivers from shore erosion and siltation, which suffocates mussels and impairs their reproductive cycle through the loss of (Bogan 1993) or access to host species through impediments to fish passage. Documenting the resident and transient fish assemblages in the Project-affected areas is critical to understanding potential impacts to freshwater mussel populations, including state- and federally-listed freshwater mussel species such as the Dwarf Wedgemussel, Yellow Lampmussel, and Eastern Pondmussel. The larvae of freshwater mussels must attach to the gills or fins of a suitable fish host in order to develop into juveniles. The suitability of the host fish is a complex relationship between mussels and fish, and research has found that even closely related fish species do not enable adequate survival of mussel glochidia.

<u>Freshwater Mussel</u>	<u>Glochidial Host Fish</u>
Dwarf Wedgemussel	Tessellated darter, Johnny darter*, mottled sculpin*, slimy sculpin, (Michaelson & Neves 1995); juvenile and parr Atlantic salmon (B. Wicklow, Saint Anselm College, unpublished data)
Yellow Lampmussel	White perch, yellow perch; recent studies have suggested that banded killifish, chain pickerel, white sucker, smallmouth bass, and largemouth bass may serve as potential hosts (Kneeland and Rhymer 2008)
Eastern Pondmussel	Unknown; reported to parasitize centrarchids (sunfishes and bass) as well as banded killifish

*Fish species not found in Massachusetts

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

As adult mussels are largely sessile, and some amount of glochidia drift in the currents (Schwalb et al. 2010), the transportation of the glochidia via the host fish is believed to be a critical element of ensuring genetic flux between populations and colonization/re-colonization.

The tessellated darter is one of only three fish species in the Upper Connecticut River that serve as hosts for the glochidia of Dwarf Wedgemussel, the others being the slimy sculpin (*Cottus cognatus*) and the Atlantic salmon (*Salmo salar*) (Nedeau 2008). Tessellated darters are a relatively sedentary benthic insectivorous fish with small home ranges and short, fast bursts of speed. Tessellated darters may become the most important hosts for the Dwarf Wedgemussel in the Upper Connecticut, as both USFWS and the Division have or are in the process of ending their programs of stocking hatchery-reared salmon in the River. The Atlantic salmon was extremely rare in the Upper Connecticut River prior to stocking; in the future, even fewer juveniles and parr will be available as hosts.

Nexus to Project

Project operations have the potential to directly impact fish species life history requirements, biological interactions, and habitat quantity and quality. For example, headpond and tailwater water level fluctuations could dewater important spawning areas, limiting productivity of fish species by direct impacts to their spawning success and indirectly limiting the spawning success of forage fish species. Accordingly, a thorough understanding of the current fish assemblage structure and associated metrics are needed in order to examine potential Project impacts. Determining species distribution and abundance will better clarify what species occur in the Project area, spatially and temporally, relative to habitats that may be affected by Project operations.

In addition to direct impacts to state-listed fish species, both current and proposed Project operations have the potential to indirectly affect state-listed mussel populations by affecting the abundance, distribution, and movements of their glochidial fish hosts. This is especially true given that the TFD and its associated operations may act as a barrier to the dispersal of resident fish species; indeed, studies have consistently demonstrated that passage through the Cabot and Spillway fishway structures is poor (Kenneth Sprankle, USFWS, personal communication). The tessellated darter, in particular, does not typically disperse great distances, which suggests that the TFD may significantly impact the ability of Dwarf Wedgemussel to recolonize and sustain populations in otherwise suitable riverine habitats. It is likely that the maintenance and recovery of rare mussel populations in the Upper Connecticut River more broadly may depend on facilitating effective passage of host fish species.

The information requested through this study will help assess how the Project has and will affect the structure, distribution and abundance of state-listed fish and freshwater mussel species, and help the Division develop recommendations that will protect and/or enhance populations of each species.

Proposed Methodology

An accepted and robust field sampling design (e.g., as described in Pollock et al. 2002 or MacKenzie et al. 2006) and accepted methods for collecting fish species likely to be present in the Project-affected areas (Bonar et al. 2009) should be used to conduct field surveys. Randomly sampling multiple habitat types using a multi-gear approach will be required to ensure that all fish species present are sampled. The spatial scope of the study will be from the headwaters of the Turners Falls Impoundment downstream to Sunderland, Massachusetts, but may omit the Upper Reservoir of Northfield Mountain Pump Storage Project. Sampling should occur at each selected site across multiple seasons (spring, summer, and fall). Digital photographs should be taken to avoid misidentification of certain species, such as Cyprinids. This will be a one year study provided river discharge conditions fall within 25th to 75th percentile for weekly averages. Based upon this study's results, and the additional information obtained on requests to survey aquatic habitats and littoral zone fish spawning, an additional study may be required if evidence of project operation affects on population status or habitat for identified species.

The sampling design should include replicate samples for estimation of species detection probability. Sample replicates may be gathered temporally, using different methods, by independent observers, or by randomly sampled spatial replicates (MacKenzie et al. 2006). For each replicate sample, data that may be important for describing variation in species occurrence and presence/absence should be collected and recorded, such as gear type, mesohabitat type, depth, velocity, flow, water temperature, substrate, time of day, day of year, presence of cover, proportion of vegetation cover, size of individuals collected (juveniles may select different habitat), and/or other factors as determined by a qualified biologist. Species detection, occurrence, and/or abundance and related habitat

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

measures on these parameters should be estimated using methods as described by Kery et al. (2005), MacKenzie et al. (2006), Wenger and Freeman (2008), or Zipkin et al. (2010).

Sampling to assess the occurrence and abundance of encysted larvae of state-listed mussel species on known and potential host fishes will require collection and analyzing gill samples. Sampling across multiple seasons is necessary in order to capture the variable timing of glochidial release, which differs seasonally between target mussel species. Collection may occur in conjunction with fish assemblage field surveys, as described above, from both above and below the TFD. Identification of mussel larvae to species level would require additional lab analysis of fish gill samples, and can utilize techniques based on morphological analysis (Kennedy & Haag, 2005; Zieritz and Aldridge 2009; Zieritz et al. 2010; Zieritz and Aldridge 2011), or molecular analysis, such as DNA barcoding or identification keys based on restriction fragment length polymorphisms (RFLP) (Zieritz et al. 2012). Field-samples of glochidia should be field-collected from gravid females of each target species to serve as references for identification, which can be collected concurrent with the requested mussel survey (see Study Request No. 20).

Level of Effort and Cost

The cost of the fish assemblage study will be moderate to high as seasonal sampling with several types of gear will be required. However, cost will also be partially dependent on the number of sites sampled, the number of sample replicates, and the extent of the covariate data that are measured, all which may be flexible. Based on first year study results, a second year of sampling or specific studies examining impacts of project operations on specific fish species may be needed and requested. Provided the collected data are of high quality, analysis and synthesis should take approximately 10-20 days.

The cost of the glochidia assessment will likely be moderate. Portions of this study (collection of fish samples) can be performed in conjunction with the broader fish assemblage study, which may reduce overall cost. Assessment and identification of mussel glochidia will depend on the number of sample replicates, which may be flexible, and technique selected for identification. Studies should be developed in consultation with the Division.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 22.
Assessing Operational Impacts on Emergence of State-listed Odonates in the Connecticut River and Northfield Mountain Upper Reservoir

Goals and Objectives

The goal of this study is to quantify the impacts of water level fluctuation on emerging teneral odonates in the Northfield Mountain Pumped Storage Project's Upper Reservoir, the Turners Falls Dam (TFD) Impoundment, and the 13+ miles of riverine habitat below the TFD (to the Rt. 116 Bridge in Sunderland). Study should include both field surveys as well as a river flow model(s) that evaluate the relationship between Project operations and water surface elevations. The specific objectives of this study are:

- A. To obtain baseline information on which state-listed odonates inhabit and are emerging within the Northfield Mountain's Upper Reservoir, the TFD Impoundment, and the 13+ miles of riverine habitat below the TFD.
- B. To determine if current water level fluctuations permitted under the TFD and Northfield Mountain Project licenses affect the abundance, composition, and distribution of state-listed rare odonate populations, and whether these populations can be protected and/or enhanced through modifications to Project operations or other mitigation measures.

Relevant Resource Management Goals

The conservation and protection of odonate species state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act (MESA) (M.G.L. c. 131A) is an important objective of the Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), as well as the rare wildlife species provisions of the Massachusetts Wetlands Protection Act (WPA) (310 CMR 10.59). The Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations

Our study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, protection, mitigation and enhancement measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), the MESA, and the WPA.

Public Interest

The requestor is a fish and wildlife resource agency, with regulatory authority under the MESA and the WPA.

Background and Existing Information

The Project generates power in a peaking mode resulting in significant within-day flow fluctuations between minimum release and project capacity on an hourly and daily basis. The current license also permits up to a nine (9) foot change in pool elevation within the TFD Impoundment. The PAD notes that FirstLight would like to expand its Upper Reservoir capacity (by up to 24%), but it is not known how this may affect the magnitude and rate of water level fluctuations. The PAD also notes that water is typically pumped to the Upper Reservoir in the evening and then is directed back to the Connecticut River once or twice daily (during the day), based upon power needs and value. Provided that set thresholds for minimum flow and TFD Impoundment elevations are met, Northfield Mountain Power Station may operate with no restrictions on the timing, frequency, or magnitude of pumping, generation, or pool elevation within the Upper Reservoir.

Previous surveys on the Connecticut River in Northfield and adjacent towns in Massachusetts have established that rapid water level changes resulting from motorboat wakes and other factors can wash away or damage emerging odonate tenerals. There is limited data available regarding the details of emergence, including how high above the

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

water emergence takes place, how long the process takes, what substrates are typically used, and how these factors differ by species or family groups. It is known, however, that emergence from larval wetlands is considered one of the most perilous stages of the odonate life cycle. Therefore, it is likely that large, rapid changes in water elevation and/or flow dynamics – where the magnitude and rate of water level increase exceeds the capacity of teneral to successfully complete the emergence process - may cause adverse effects to the life cycle of state-listed odonates, and particularly, the emergence of teneral. This, in turn, may impact the abundance, composition, and distribution of state-listed odonate populations in the central Connecticut River.

It is generally known which state-listed odonate species inhabit the Connecticut River in the vicinity of the TFD as larvae. However, it is not known exactly which species inhabit stretches of the River as differentiated by depth, substrate, speed, and other factors, such as the deep, ponded stretch immediately above the TFD in Barton's Cove or the fast, rocky, relatively shallow stretches below the TFD. Nothing is currently known about which odonate species, whether rare or common, inhabit the Upper Reservoir as either larvae or adults.

Nexus to Project

The Project is currently operated with minimum flow releases and head pond fluctuations that were not based on biological criteria or field study. The timing, rate, and magnitude of releases from the TFD, including water level fluctuations within the TFD Impoundment and the Northfield Mountain's Upper Reservoir, may have direct, adverse effects on emerging odonate teneral. In order to fill this important information gap, an empirical study is needed to provide information on the relationship between the proposed mode(s) of operation and the effects of water level changes on emerging odonate teneral. Results will be used by the Division to determine appropriate recommendations to protect and/or enhance state-listed odonates and their habitats.

Proposed Methodology

Surveys of larval odonates via exuviae collection, dredging, and visual surveys are standard methodologies for studying odonate populations. In the Upper Reservoir, the Impoundment, and downstream of the TFD on the river, these surveys will concentrate on exuviae collection and dredging for nymphs. In the Upper Reservoir, surveys will also include visual searches for recently emerged odonates, especially damselflies, near the water's edge.

Surveying for exuviae involves methodical visual searches of appropriate substrates near (typically, within 10 feet) the river's edge. Appropriate substrates vary by species, and because there is some degree of within-species variability, these may include sand, silt, rocks, trees, coarse woody debris, undercut banks, tree / plant roots, and anthropogenic structures such as bridge abutments or walls. Visual surveys should be carried out every day, starting at dawn. Most odonates emerge at night, and wind, rain or water level changes can remove exuviae quickly if they're not located in protected sites. Surveying for nymphs via dredging also depends on the species. Sand/silt/cobble dwellers can be adequately sampled for presence/absence by kick-netting. Species that cling to coarse woody debris or to rocks/concrete need to be sampled by visual inspection (which might involve diving). Surveying for recently emerged adults would involve visual surveys by a qualified biologist along the water's edge.

Qualified biologists will need to survey for odonates at a suite of sites up- and downstream of the TFD at several times during the field season to catch the emergence peaks of state-listed odonate species. Because odonate species may differentially emerge within different habitat types, surveys should assess emergence across a range of depths, substrates, water velocities, and other factors. Finally, to make the connection (if any exists) between Project operations and odonate emergence, the study will need to determine the elevation of nymphs relative to the water surface when they initiate emergence, how long emergence takes, and both the magnitude and rate of water level fluctuations.

The height of water levels will need to be cataloged during the field season, but the magnitude and rate of water level change will likely need to be addressed through the development of river hydrology statistics and modeling, which are commonly employed at hydroelectric projects to assess the effects of project operations on the river environment. Field survey results, as described above, should be combined with the results of a river flow model(s) that evaluate hydrologic changes in the Connecticut River due to existing and proposed Project operations, as requested in related studies by the Division. Modeling should enable the quantitative assessment of how water surface elevations within the Northfield Mountain's Upper Reservoir, the TFD Impoundment, and the reaches downstream of the TFD are affected by discharges from the TFD, pumping into the Upper Reservoir, and their

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

associated generating facilities. Field assessments may be required to collect flood depth, timing, duration, frequency and changes to substrate to inform the model. Such measurements should be taken over a range of test flows, between existing minimum flows and maximum project generation flows, and should be synthesized to quantify how water surface elevations change.

Level of Effort and Cost

The field assessment portions of this study will be moderately time- and cost-intensive; the cost is entirely dependent on the number of sites, number of sample replicates, and the extent of the covariate data that are measured, all of which may be flexible and determined through consultation with the Division.

Level of effort and cost for model development are expected to be moderate, and running of various scenarios through the model(s) may be needed throughout the relicensing process to assess the implications of changes to Project operations. However, because similar models have been requested as part of other study requests, the modeling portion of this study may not represent a significant increase in effort.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Requested Study No. 23.
Assessing Operational Impacts on State-listed Rare Plants in the Connecticut River

Goals and Objectives

Conduct a study to quantify the impacts of water level fluctuations on state-listed rare plant species in the Turners Falls Dam (TFD) Impoundment, as well as current and proposed flow regimes in the 13+ miles of riverine habitat below the TFD (to the Rt. 116 Bridge in Sunderland)..

The specific objectives of this study are to:

- A. Obtain baseline information, through field surveys, on the locations and population parameters of Massachusetts state-listed rare plant species in the TFD Impoundment and the 13+ miles of riverine habitat below the TFD (to the Rt. 116 Bridge in Sunderland).
- B. Assess how current and proposed Project operations affect existing habitat for, and the growth, survival, and reproduction of state-listed plant species inhabiting mud flats, sand bars, and high energy shore and cobble island habitat types, including (but not limited to) the following:
 1. Mountain Alder (*Alnus viridis ssp. crispa*) – “Threatened”
 2. Tufted Hairgrass (*Deschampsia cespitosa ssp. glauca*) – “Endangered”
 3. Wright’s Spike-rush (*Eleocharis diandra*) – “Endangered”
 4. Intermediate Spike-sedge (*Eleocharis intermedia*) – “Threatened”
 5. Ovate Spike-sedge (*Eleocharis ovate*) – “Endangered”
 6. Frank’s Lovegrass (*Eragrostis frankii*) – “Special Concern”
 7. Upland White Aster (*Oligoneuron album*) – “Endangered”
 8. Sandbar Cherry (*Prunus pumila var. depressa*) – “Threatened”
 9. Sandbar Willow (*Salix exigua ssp. interior*) – “Threatened”
 10. Tradescant’s Aster (*Symphotrichum tradescantii*) – “Threatened”
- C. Assess how current and proposed Project operations affect potential habitats for state-listed plant species exhibiting meta-population dynamics, as further described below, including Wright’s Spike-rush, Intermediate Spike-sedge, Ovate Spike-sedge, Frank’s Lovegrass, and Tufted Hairgrass.

Relevant Resource Management Goals

The conservation and protection of populations and habitats for the 256 species of plants state-listed as Endangered, Threatened, or of Special Concern under the Massachusetts Endangered Species Act is an important objective of the Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries and Wildlife. State-listed species and their habitats are protected pursuant to the MESA and its implementing regulations (321 CMR 10.00), and the Division seeks to accomplish the resource goals and regulatory requirements of the MESA in order to:

- Ensure that protection, mitigation and enhancement measures are commensurate with Project effects and meet MESA requirements for the Project.
- Conserve, protect, and enhance the habitats for state-listed species that will be affected by Project operations.

Our study requests are intended to facilitate the collection of information necessary to conduct impact analyses and develop reasonable conservation, protection, and mitigation measures pursuant to the Fish and Wildlife Coordination Act, as amended (16 U.S.C. §661 *et seq.*), the Federal Power Act (16 U.S.C. §791a, *et seq.*), the Clean Water Act (33 U.S.C. §1251 *et seq.*), and the MESA.

Public Interest

The requester is a state natural resource agency, with regulatory authority under the MESA.

Comments of the Massachusetts Division of Fisheries and Wildlife
Northfield Mt Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889)

Background and Existing Information

It is generally known which state-listed plant species inhabit the Connecticut River in the vicinity of the TFD. The PAD provides a list of plant and wildlife species whose native ranges overlap with the Project-affected area, but it does not provide baseline information on known occurrences of state-listed plant species. Several surveys along this stretch of the River by professional and volunteer botanists have shown that many of these species are dynamic; local populations often display meta-population dynamics, changing in size and location from year to year. This is particularly true of plants species inhabiting sand bars and high energy shore and cobble islands, including (but not limited to) the state-listed Wright's Spike-rush, Intermediate Spike-sedge, Ovate Spike-sedge, Frank's Lovegrass, and Tufted Hairgrass.

Large and/or rapid changes in water elevation and/or flow dynamics may cause adverse effects to existing and potential habitat for state-listed plants. More broadly, Project operations may also adversely affect the life cycle of state-listed plants, and in particular, the germination, growth, and dispersal of species inhabiting mudflats, sand bars and cobble islands. However, these effects are poorly understood and the Division is not aware of any studies that have evaluated these effects.

Nexus to Project

The Project is currently operated with minimum flow releases and head pond fluctuations that are not based on biological criteria or field study. Large, rapid changes in flow releases from hydropower dams are known to cause adverse effects on habitat and biota downstream of such facilities. The timing, rate, and magnitude of releases from the TFD, and the water level fluctuations in the TFD Impoundment, may have direct, adverse effects on rare plant populations and their habitats. In order to fill this important information gap, an empirical study is needed to provide information on the relationship between the proposed mode(s) of Project operations and the quantity and quality of state-listed plant habitat in the Connecticut River. Results will be used by the Division to determine appropriate operational recommendations to protect and/or enhance state-listed plants and their habitats.

Proposed Methodology

Field surveys, within appropriate habitat types, should involve visual surveys during appropriate phenological windows via transects, meander survey, or fixed plots. In addition, the rate and height of water level changes resulting from Project operations during the field season will need to be cataloged. Surveys should collect information regarding location, elevation, and population size, extent and condition, and should occur monthly in order to assess the effects of seasonal flow dynamics on documented individuals and populations. To make the connection (if any exists) between Project operations and the life-cycle of rare plant populations, biologists will need to determine when rare plants start growth and assess how long it takes for maturation and seed dispersal to occur.

River hydrology statistics and modeling are commonly employed at hydroelectric projects to assess the effects of project operations on the river environment. Habitat assessments are also a common tool in developing operational regimes that will reduce impacts or enhance habitat conditions up- and down-stream of hydroelectric projects. Field assessments should involve collecting flood depth, timing, duration, frequency and changes to substrate characteristics along the mainstem of the Connecticut River. Data collected should be sufficient to permit assessment of how the quality, extent, and location of existing and potentially suitable habitat for known populations – and for species exhibiting meta-population dynamics, as described above - changes over a range of flows. The measurements should be taken over a range of test flows, between existing minimum flow and maximum project generation flows, and synthesized to quantify habitat suitability under each test flow.

Level of Effort and Cost

In the PAD, FirstLight identified impacts of the Project operations on wetlands, riparian and littoral zone habitat as a potential issue to be addressed in relicensing. However, additional analyses are needed to understand the impacts of the Project on rare plants and their habitats more broadly. The study proposed here will be moderately time- and cost-intensive. However, the cost is entirely dependent on the number of sample replicates that will be surveyed and measured, all of which should be determined in consultation with the Division.

Low water hampers use of Connecticut River

Jeopardizes potential river rescue response

By CHRIS CURTIS
Recorder Staff

TURNERS FALLS — Shallow water on the Connecticut River annoyed boaters and worried emergency responders Sunday.

The Northfield Dive and Rescue Team's annual lobster bake fundraiser brought together both categories of river-users at the Turners Falls Rod and Gun Club.

The club facility, at 15 Deep Hole Drive on the bank of the Connecticut River, includes two docks for members and a slope cleared for use as a boat ramp.

Much of the slight cove by the club had the look of a mossy field Sunday morning and afternoon, with aquatic plants and normally submerged stumps left high and relatively dry.

See LOW Page C3

Photo/Chris Curtis

Turners Falls Rod and Gun Club member Bruce Merriam of Turners Falls stands in front of the channel from the club boat ramp to the Connecticut River. Unusually low water blocked members from using the river Sunday.

From Page C1

Water remained in the channel but club member Bruce Merriam said his power boat could never cross the shallow stretch to the river.

Merriam, of Turners Falls, blamed FirstLight Power Resources, the utility operating the nearby dam.

"They ruined one day of boating for me and boating season is short in New England," Merriam said.

Merriam estimated the water level was down about five feet, not the lowest he had seen in his years with the club but the lowest for the year.

Rescue response time

Bill Ryan of the Northfield Dive and Rescue Team said the low water could slow a potential rescue.

"It's not like we couldn't access the river but it would slow things down," Ryan said. "When you do a water rescue timing is everything, so every second counts."

Ryan said the ramp is one of two used by his group, the other being the public boat ramp in Gill.

Turners Falls Fire Capt. Leon Ambo said his department usually launches their rescue boat from the club ramp and was not confident the boat could clear the channel.

Ambo said he had seen the water level on a Sunday afternoon news broadcast, and had never seen the water so low.

"After seeing that on the news, I probably would head over to Gill," Ambo said. "If it was an emergency call, I don't think we would try it."

By 8 p.m., Ambo said the water level had risen sufficiently to launch.

Ryan said water levels are significantly lowered several times a year and the low levels have so far never coincided with one of the group's dozen or so annual rescue responses.

Ambo and Ryan said the utility does not notify them when lowering water levels via the power canal or dam, and Ambo said he does not believe the company has any obligation to do so.

FirstLight representatives could not be reached for comment Sunday.

Since 1876, the Appalachian Mountain Club has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. It is the largest conservation and recreation organization in the Northeast with more than 90,000 members.

Riverwide issues: cumulatively effected resources and incremental effect of licensing the five Connecticut River projects with other past, present and reasonably foreseeable future actions within the Connecticut River Basin. Comments and suggestions on issues and alternatives to be addressed in the EIS and studies that will help provide a framework for collecting pertinent information on the resource areas.

The AMC's interests in hydropower relicensing are mainly in the areas of conservation and recreation. We want to help TransCanada and FirstLight in preparing their license applications by improving their contributions to conservation and recreation.

We have an interest in the creation of improved opportunities for multiple-day canoe and kayak trips on the Connecticut River. New England generally does not have a lot of opportunities for multiple-day canoe trips when compared to other regions of the country, with the exception of areas of northern Maine such as the St. John and Allagash Rivers, which are many hours from population centers. The Connecticut River runs from northern New Hampshire to Long Island Sound. It passes through several population centers and is easily accessible from all the major cities in New England with populations in the millions.

AMC Riverwide Issues Comments

The most serious obstacles to multiple-day trips are the hydropower dams themselves. The existing portage routes around the dams are grossly inadequate, too long, and dangerous. For example, the Bellow's Falls portage route is 1.5 miles long and for much of that distance follows the breakdown lane of a high-speed state highway. The only portage around Turner's Falls comes from calling the power company and requesting a truck. Campsites are scarce in Massachusetts. Access areas are closed for much of the year.

We need a study of the facilities that are necessary for canoe access to the river. Most of the existing facilities were designed for day use by motorboats. The ramps and other facilities are not particularly suited to canoeists, particularly those using wood-and-canvas canoes. Campsites are sometimes completely filled up by parties that arrive in motorboats and stay for a week.

We recommend a study of the quantity, quality, and adequacy of the land-based facilities associated with boating on the Connecticut River. This interest involves all of the facilities that are being relicensed. The study should coordinate all the facilities even though there are two hydropower owners. Flow changes that benefit recreation might have a generational impact on all the dams lower on the river. This study should examine put-in and take-out facilities especially for canoeing and kayaking, portage routes, campsites, parking and road access, seasons of operation, maintenance, and sanitary facilities. The study should include a projection of usage during the 30-year life of the licenses, and the opportunities for the project owners to buy land in order to increase recreational benefits.

In association with the above study, a study of the creation of the Connecticut River and Watershed National Blueway should be done, along with ways that the existing hydropower facilities can contribute to that effort.

On May 24, 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. A Memorandum of Understanding signed in August by the departments of Interior, Agriculture, and the Army has as one objective "providing opportunities for scientific research, environmental education and outdoor recreation and access within the National Blueway to the extent compatible with agency missions." The National Blueway concept takes a watershed viewpoint and addresses the river from its source to the sea. The National Blueways System has as its goal "to advance a whole river and watershed-

AMC Riverwide Issues Comments

wide approach to conservation, outdoor recreation, education, and sustainable economic opportunities in the watersheds in which we live, work, and play.” The National Blueway designation includes all the tributaries in the watershed and involves several federal agencies.

The National Blueway engages several federal agencies including the U.S. Army Corps of Engineers, the Silvio Conte Refuge, U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration in the 7.2 million-acre Connecticut River Watershed.

Off-site mitigation for the loss of whitewater habitat by these four dams on the mainstem Connecticut River might take place on tributaries such as the West River, where the U.S. Army Corps of Engineers controls the flows. According to an MOU among Interior, Agriculture, and the Army signed in August, the Corps of Engineers “owns and operates 14 flood control dams and manages about 20,000 acres in the watershed to better manage the water supply, provide flood control and hydropower generation, and support recreation and environmental stewardship.” Opportunities to engage these federal agencies and help them meet their obligations under the National Blueway System should be part of this study.

The Connecticut River Paddlers Trail and the Connecticut River Birding Trail cross several project boundaries. Their interests should be part of a framework that takes a river-wide viewpoint.

We have an interest in trails nearby and associated with project lands. A study should evaluate the adequacy and maintenance of existing trail systems for the next 30 years, and determine opportunities for additional hiking trails on project lands, and linking those trails to existing trails. Such trails in the watershed could cross project boundaries, and adding to them could involve requiring the Licensees to purchase additional land.

PUMPED STORAGE PROJECT, FERC PROJECT NO. 2485-063.**

Since 1876, the Appalachian Mountain Club (AMC) has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region. The AMC is a steering committee member of the Hydropower Reform Coalition based in Washington, D. C. The AMC is the largest conservation and recreation organization in the Northeast with more than 90,000 members, many of whom live within three hours of the Connecticut River and would enjoy this section as a daylong or longer trip. The AMC's interests in hydropower relicensing are mainly in the areas of conservation and recreation.

The Vermont River Conservancy protects public access, wildlife habitat, clean waters, scenic natural beauty and ecological integrity by conserving undeveloped land along rivers, lakes and wetlands of Vermont. Since 1995, working in cooperation with state and federal agencies, municipalities and other conservation organizations, VRC has completed projects at over 45 popular local swimming holes, gorges and waterfalls, fishing and boating accesses, protecting paddlers' trails and meandering river corridors for all to enjoy.

The Friends of the Connecticut River Paddlers' Trail is dedicated to building and stewarding primitive campsites, access points, and portage trails along the Connecticut River. The organization manages over 30 campsites and 70 access points that reach from the Connecticut River's headwaters south to the Massachusetts border. Efforts are underway to expand the trail into Massachusetts and Connecticut. The group includes representatives from conservation organizations, state and federal agencies, hydroelectric companies, and town conservation commissions that recognize the region's rich ecology and productive working landscape and seek to facilitate recreational use compatible with the Refuge's natural, social, and historic character.

Currently five hydropower projects on the Connecticut River are up for new federal licenses, with Turners Falls Dam the farthest south. These five facilities influence about 168 miles of the longest river in New England, including creating 91 miles of reservoir that have fragmented the river and converted whitewater rapids into impoundments. The impacts stretch from the upper reaches of the 45-mile long Wilder Project reservoir in New Hampshire and Vermont down to about Northampton, or possibly the Holyoke Dam reservoir, in Massachusetts. The watershed surrounding these projects encompasses a significant portion of the 7.2 million acres in the Connecticut River and Watershed National Blueway. The main stem is of sufficient size for canoeing, kayaking and rowing for multiple-day trips, and flows through beautiful Appalachian countryside.

Rather than repeating some requests here, the AMC co-signed onto American Whitewater and New England FLOW's study requests for whitewater recreation and contingent valuation economic studies and hereby references them without repeating them in detail for brevity's sake. This includes controlled-flow studies as have been done on dozens of FERC projects, specifically at the bypass reach below the Turners Falls Dam. The recreational values there would be improved by scheduled releases. On- or off-site mitigation for loss of whitewater should also be evaluated in relation to the loss of whitewater above the Turners Falls Dam, whose reservoir reaches all the way to Vernon Dam in Vermont and New Hampshire.

In the following study requests, we additionally address impacts of and study needs for the Turners Falls and Northfield Mountain Projects, including issues of multiple-day river trips, flow diversion issues, historical and cultural resources, recreational concerns, and the financial health of the operator and decommissioning funds.

All studies requested here should contain projections for use by the public during the 30-year life of the proposed license, and the adequacy of all facilities and mitigation for that time period, as well as how existing impediments discourage public use currently.

In addition to recreation and aesthetics, we recognize that flow-related decisions also affect economic factors related to power generation and other environmental variables. We look forward to exploring how all flow values relate to one another through participation in this relicensing process.

Our study requests address impacts of the Turners Falls and Northfield Mountain projects, including issues of multiple-day river trips including the lack of the portage trail, the opportunities for whitewater recreation in the bypass reach, historical and cultural resources, recreational resources at Northfield Mountain, and the financial health of the facilities and decommissioning funds.

Issue #1: Impacts of Project Dams on Multiple-Day Self-Propelled Trips on the Connecticut River.

In the scoping area of recreation, the AMC has an interest in the creation of improved opportunities for multiple-day canoe and kayak trips on the Connecticut River, along with facilities that would also accommodate rowing shells. When compared to other regions of the country, New England generally does not have a lot of opportunities for multiple-day canoe trips with the exception of several rivers in far northern Maine, such as the St. John and Allagash, which are many hours from population centers. The Connecticut River runs from northern New Hampshire to Long Island Sound. It passes through several major population centers and is easily accessible from all the cities in New England as well as the greater New York City area with populations in the millions.

The most serious obstacles to multiple-day trips on the Connecticut River are the hydropower dams themselves. The Turners Falls dam owned by FirstLight blocks the river to downstream navigation. Access points and campsites are inadequate. Additional land-based amenities should be added such as potable water, toilets, and campsites that would be used by paddlers engaged in multiple-day trips on the river.

One could say there is no portage pathway around the dam, or that it is conspicuously bad. The current portage route is unmarked and the longest along the river. The boat launch at Barton Cove is also the take-out location for the portage around Turner's Falls Dam. It is a 3.5-mile portage that requires traveling on busy highways with guide signs. The power company will provide a free shuttle to those who call ahead, but information about this shuttle service is limited. In addition, the frequency of this service is somewhat limited. It is also necessary to develop a safe and signed portage trail route for paddlers seeking to self-shuttle.

Access below the Turner's Falls Dam is inadequate. The official launch (Popular Street Launch) is a steep, eroding slope that is a hazard to paddlers. Most locals choose instead to launch on adjacent, private property where access is much easier. However, this land is posted, private land. Further work is needed to improve the situation here.

First Light provides two camping facilities along the river. These facilities are inadequate to meet the growing demand. There is a need to establish additional campsites, especially in the 65-mile section below Turners Falls where no official campsites have been developed.

In preliminary application documents, the Licensee cited the Massachusetts SCORP (2006-2011), which indicated a need for "water-based" activities. Multiple-day canoe, kayak or rowing trips certainly meet the needs identified in the SCORP documents, but such trips are severely limited by the operations of the Turners Falls hydropower dam.

Facilities such as campsites and boat ramps do exist, as detailed in the PAD. But for multiple-day trips, or for paddlers or rowers seeking to navigate the length of the Connecticut River, the dams and lack of campsites discourage such travel. Fisheries

biologists have suggested that migrating fish tire after the second fish ladder. Canoeists faced with the cumulative obstacles presented by the hydropower dams become similarly discouraged and abandon their efforts to migrate downriver.

River travelers find that the Turners Falls Dam is the largest impediment to through-travel. In addition, users are at the site of a major historical event in American life, yet the power company gives no indication of that. See Issue #3 below.

In its PAD, the Licensee proposes no enhancements to mitigate the project effects on multiple-day canoe and kayak recreational use.

Issue #2: Impacts of the Connecticut River Flow Diversion on Recreational Paddling at the Turners Falls Bypass Reach.

We recommend a controlled-flow study of whitewater in the Turners Falls bypass reach. The Turners Falls bypass section of the Connecticut River has the potential to offer quality whitewater paddling opportunities during scheduled events. At moderate and higher flows, a few boaters who can gain access to the river currently use the bypass reach to surf waves to paddle this 2.7-mile whitewater section.

In addition to kayaking, this reach has potential for rafting, guided kayaking, canoeing, instruction, and general paddling use. Collectively the recreational use of the resources at this project has the potential to add economic value to the region if the releases were scheduled and predictable. The bypass reach has close proximity to the University of Massachusetts, Holyoke and Greenfield Community Colleges, and the Northfield-Mt. Hermon School. Millions of people live within a three-hour drive of the Turners Falls facility.

Access to the bypass reach is extremely problematic. Fences have been installed to make access even more difficult. With enough scrambling, a kayaker can make it to the river left side, but the more desirable right side is steep, fenced off, and has little parking. No access stairs exist. Similarly, the take-out downstream at the confluence with the Deerfield River is steep, frequently muddy, and often unusable.

Any bypass reach such as this one presents aesthetic issues as well. A nearly dry natural riverbed is ugly. Daytime aesthetic flows during the spring, summer, and fall could give the public a glimpse of what the natural river looked like before the dam.

The current operation of the project eliminates valuable seasonal paddling opportunities. In the PAD, the Licensee proposes no flow enhancement to mitigate the project's effects on whitewater recreational use.

In addition to recreation and aesthetics, we recognize that flow-related decisions also affect economic factors related to power generation, fish passage, and other environmental variables. We look forward to exploring how all flow-related values relate to one another through participation in this relicensing process.

Issue #3: Cultural, Historical, and Educational Resources.

The Turners Falls Dam creates a number of special and distinctive issues that can be improved during relicensing. The reservoir covers much of the scene of a significant event in American history, yet the Licensee does not have educational and interpretative signs that would allow visitors to understand that history.

In May 1676, colonial forces under the command of Capt. William Turner attacked an Indian village across the river from the current town of Turners Falls. Many of the inhabitants were slaughtered, especially women and children. Some of the men escaped. They returned with friends and pursued the retreating English forces, killing Capt. Turner. Historical artifacts may still exist at the site, much of which has been submerged beneath the Turners Falls Dam reservoir. A study should be done to determine a variety of options for educating the public about the site, and to determine what actions should (or should not) be taken to preserve artifacts.

Informational signage and kiosks at project facilities should promote education about historical events as well as invasive species, water flows, the history of the area, who to call with problems, and what to do to get involved. Educational improvements should be coordinated with recreational improvements. Some people have suggested that a walkway be constructed on the north or river right side at Turners Falls with interpretative materials. Such a walkway could help solve two other major issues with the dam: the lack of a portage pathway around it, and the difficulty of accessing the bypass on river right.

A second historical issue involves the records of construction of the Turners Falls dams and the Northfield Mountain Pumped Storage facility. The engineering studies, drawings, and photographs taken during construction are of historical importance now and should be preserved. The first dam at Turners Falls was attempted in 1792 but washed away. A substantial timber-crib dam was constructed in 1865. The first concrete dam was built in 1909-1912. The current dam was built in 1969-71 on the Gill side and on the Turners Falls side the old dam was retrofitted with new gates. This relicensing offers perhaps a last chance to rescue important historical records held by the Licensee related to the design and construction of the hydropower facilities as well as historical, pre-project conditions. A study should determine what historical records remain, make suggestions for their safe storage, for how they can be made publicly accessible, and for improvements at the project to highlight the historical significance of the facilities to the public

Issue #4: Recreation at Northfield Mountain.

At the Northfield Mountain Pumped Storage project, the original Licensee created a wonderful recreation area. It has been perhaps the premier regional cross-country skiing site during the winter, when there is sufficient snow, and many activities take place

during the warmer months. This is exactly the kind of facility that Licensees should be providing.

Unfortunately at Northfield Mountain cutbacks have trimmed the staff. The facilities along the river shut down way too soon in the fall and do not offer night skiing during the winter. Low-snow years have limited cross-country skiing. A study should be done to recommend improvements and additions that would return Northfield Mountain to the intent of its original license as well as providing for greater amenities for the future license.

A parent and manager of the nearby Amherst High School Nordic Ski Team began an email by saying, "Northfield Mt. is a treasure. There are beautiful hiking, snowshoeing and cross-country trails and the grooming of the ski trails is excellent." But then she added, "The mountain needs lights for night skiing and the ability to make snow. Currently, the mountain is closed on Monday and Tuesdays and closes at 4:30 PM. Our team skis after school, arrives at Northfield around 3 PM and can only ski for an hour and half although there is adequate light to ski for longer. Often the mountain is closed when there is snow on upper trails, but not lower trails. Also, Northfield should be available to host high school Nordic ski meets. Currently they are unwilling to do this. Northfield Mt. would be an ideal place to make snow. There is no trouble accessing water and the lower trails are in the shade and would hold snow for a long period of time. A five kilometer loop of man-made snow would be ideal. This would allow for skiing throughout the season and would make Northfield Mt. a truly valuable resource for outdoor recreation in Massachusetts."

The Applicant needs to analyze what operational hours will best meet users' needs and expectations and consider snowmaking for early cross-country skiers before any big winter storms can cover the trails.

There are equally important issues at Northfield Mountain concerning trails of national significance. The New England Scenic Trail (NET) runs through project lands at Northfield Mountain. The New England National Scenic Trail is a 215-mile trail in Connecticut and Massachusetts that received federal designation in 2009. FirstLight has agreed that a relocation of the NET within project boundaries would provide an enhanced recreational experience and level of safety for the public. There are significant climbing areas nearby that would be more accessible after the relocation of the NET. A recreational study could provide assistance in both cases, possibly by recommending that the Licensee buy nearby land from willing sellers to preserve the climbing areas and provide the best route for the New England Trail.

Issue #5: Economic Health and Decommissioning.

Energy markets have changed dramatically in the past decade. The ownership turnover of energy facilities has been dramatic. Climate change may cause more frequent catastrophic and extraordinary events in coming years in the Connecticut River Valley,

such as Tropical Storm/Hurricane Irene in 2011, which washed out some portion of almost every state highway in Vermont except the Interstates. With the possibilities of millennial weather events occurring with much greater frequency and the ongoing dramatic changes in the competitiveness of current energy generating sources, we believe that a study should assess the need for escrowed decommissioning funds or trust funds for all hydroelectric facilities currently up for new licenses. Many outdated and derelict dam removals today are coming at the expense of public dollars.

We recommend a study to determine the appropriate decommissioning costs at the end of this project's lifetime and how such costs should be funded in escrow in advance. In an age of international ownership, deregulation, changing ownership, and climate change, the financial health of ownership can be brought into jeopardy by distant events or by weather-related catastrophic failure of a dam. The public should not be burdened with decommissioning costs.

We hereby request five studies per 18 CFR 5.9(b).

1. Study of Project Facilities to Support Multiple-day Self-Powered Boating Trips on the Connecticut River.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

We recommend a study of the quantity, quality, and adequacy of land-based recreational facilities operated by the Turners Falls and Northfield Mountain Licensee that are associated with boating on the Connecticut River. This study should examine put-in and take-out facilities especially for canoes, kayaks, rowing shells and other self-powered watercraft; the portage route at Turners Falls Dam; campsites; parking and road access; seasons of operation of the facilities to match with actual river use; maintenance; water supplies and other amenities at campsites; and trash and sanitary facilities. The study should include a projection of usage during the proposed 30-year life of the license, opportunities for the licensee to buy land from willing sellers in order to increase and safeguard recreational benefits for the project's tenure.

The study should examine the facilities that are necessary specifically for canoe, kayak and rowing shell access to the river. Information from the state SCORP study and from other river recreational interests suggests that interest in quiet water paddling is rising along with the sales of sea kayaks, rowing shells and canoes. Most of the existing facilities were designed for day use by motorboats. Motorboat launch ramps are not particularly suited to canoeists, kayakers, and rowers, especially those using wood-and-canvas or fiberglass boats (e.g., sand works better than concrete).

Paddlers who have attempted to follow the Connecticut River to the sea report that portages and camping can be difficult, and become even more difficult once they reach Massachusetts. Campsites become few and far between. Islands are often posted as off-

limits. Many paddlers don't know that any campsites are available and end up camping on mudflats and on isolated portions of private lands. One landowner reported at a scoping meeting in Turners Falls, Mass., that he found a number of canoeists on his property one morning above the Turners Falls Dam. He shuttled them to below the dam, stopping en route to buy them breakfast at the Shady Glen diner in Turners Falls. The Licensee maintains two campsites, at Barton Cove and Munn's Ferry, both of which charge \$22 per night for a tent site and require reservations and deposits. One source-to-sea paddler was very complimentary of the Munn's Ferry site, which is for boaters and canoeists only, except that it doesn't have potable water. Competition for campsites is not uncommon, and the study might look at ways to minimize such conflicts. In the Turners Falls reach, which extends from below the Vernon Dam in Vermont to as far downstream as Northampton or even the Holyoke Dam, there are not nearly enough campsites. The Connecticut River Paddlers' Trail organization states the ideal frequency of canoe campsites is one for every five river miles, accompanied by canoe and kayak access in every town. This project falls far short of that standard.

(Photo: Jeff Feldman)

The amenities provided by the Licensee at campsites should be standardized and, at a minimum, include good canoe landing sites, toilets, potable water, trash disposal, picnic tables, and tent platforms or three-sided shelters.

The Turners Falls Dam has no portage pathway around it. If paddlers arrive at Barton Cove during working hours and have a phone, they can call for a truck to pick them up. Paddlers report the Licensee is fairly prompt and courteous in providing that shuttle service. It drops paddlers off at the mouth of the Deerfield River, which is often an unusable put-in. Still, a trail is needed in the new license if someone wants to self portage. Two opportunities exist: one on river right that might also be used for

educational displays; and one on river left along the power canal that now serves as a bike trail. A 3.5-mile portage trail is too long, and the locations of the take-out and put-in are important not only for portage reasons but also for safety reasons. This can be a tough problem and it should be closely examined in the study.

This portage problem can be a major discouragement to downriver paddlers. One through-paddler, who completed the entire river in five years by paddling one week a year, said he stopped at the Turners Falls Dam to avoid the portage. The next year he picked up below the dam.

Trails on both land and water should be studied. The Connecticut River Paddlers' Trail and the Connecticut River Birding Trail cross project boundaries. Their interests should be part of a study framework that takes a watershed viewpoint, especially as it involves trail networks and associated facilities. Trails of national significance pass through the Northfield Mountain Pumped Storage project lands in Massachusetts, including the New England National Scenic Trail (NET), a 215-mile trail in Connecticut and Massachusetts that received federal designation in 2009. FirstLight has agreed that a relocation of the NET within project boundaries would provide an enhanced recreational experience and level of safety for the public.

The ownership of project lands at all the facilities should be studied for recreational and conservation improvements. Some project lands could be added to existing park facilities, or placed under permanent conservation restrictions, in order to improve conservation and recreation. One example involves land at the Northfield Mountain Recreation Facility owned by FirstLight, where the relocation of the New England National Scenic Trail and the access it provides to popular climbing areas would benefit from the purchase of critical parcels to guarantee the long-term viability of the major recreational opportunities on or near the site. The public has an interest in trails in the vicinity of project lands. The study should evaluate the adequacy and maintenance of existing trail systems for the next 30 years, and determine opportunities for additional hiking trails on project lands, and for linking those trails to existing trails. Such trails in the watershed could cross project boundaries, and adding to them could involve requiring the Licensee to purchase additional land.

In association with this study, the creation of the Connecticut River and Watershed National Blueway should be taken into account, along with ways that the Turners Falls and Northfield Mountain projects can contribute to that effort. The study should take into consideration impacts on the entire watershed.

As part of this study, for example, a survey should seek to determine why people do NOT use this great public resource. The cumulative discouragement of recreation on the Connecticut River may displace use to other areas of the watershed. As with upstream migration of fish and downstream migration of canoeists, the survey might identify several discouraging aspects of project operations that could be corrected during relicensing.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;

None of the three requesters is a resource agency. However, several state and federal agencies have an interest in recreation and conservation on the Connecticut River.

The Commonwealth of Massachusetts owns and operates several river access areas on the Connecticut River in the vicinity of the Turners Falls Project, and thus has a clearly expressed interest in the public's ability to navigate the commonwealth's rivers.

The U. S. Fish & Wildlife Service (USF&W), National Marine Fisheries Service (NMFS) and the Massachusetts Department of Fisheries & Wildlife (MA-DF&W) have a clear interest in the passage of anadromous and other migratory fish through fish ladders at the Spillway, Station # 1 and Cabot at Turners Falls. In addition, the Conte Anadromous Fish Laboratory is located within the Turners Falls Project boundaries and is a founding organization in the National Blueway System. Although the federal Atlantic Salmon Restoration Program has been recently curtailed, some of the above agencies continue to study and promote the effective upstream and downstream passage of many endangered or threatened species.

Beyond the fisheries agencies, several federal agencies have an interest in recreation and conservation on the Connecticut River. On May 24, 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. A Memorandum of Understanding signed in August 2012 by the departments of Interior, Agriculture, and the Army has as one objective "providing opportunities for scientific research, environmental education and outdoor recreation and access within the National Blueway to the extent compatible with agency missions." The National Blueway concept takes a watershed viewpoint and addresses the river from its source to the sea. The National Blueways System has as its goal "to advance a whole river and watershed-wide approach to conservation, outdoor recreation, education, and sustainable economic opportunities in the watersheds in which we live, work, and play." The National Blueway designation includes all the tributaries in the watershed and involves several federal and state agencies, including the U.S. Army Corps of Engineers, the Silvio Conte Refuge, U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration in the 7.2 million-acre Connecticut River Watershed.

(3) If the requester is a not resource agency, explain any relevant public interest considerations in regard to the proposed study.

The hydropower dams on the Connecticut River create obstacles to public navigation and recreation on the river. Conducting the necessary studies and implementing the measures needed to ensure the public has access to quality outdoor recreational resources are in the public interest. It is widely accepted that outdoor recreation has significant benefits to

participants including health, well being, and quality-of-life. Outdoor recreation also has proven economic benefits for communities located near recreational resources.

Improvement in opportunities for multiple-day canoe, kayak and rowing trips on the Connecticut River has the potential to offer the region significant economic benefits.

Project operations have created serious aesthetic issues along the route of the Connecticut River. The dry bypass reach at Turners Falls is an aesthetic blight on the river. Even worse, the dams have substituted their industrial appearance for the naturally scenic rapids and falls that once graced the Connecticut River. The public has an interest in the scenic values of this major public resource.

1841 drawing of Great Falls (now Turners Falls) by Orra White Hitchcock (Courtesy Ed Gregory archive)

(4) Describe existing information concerning the subject of the study proposal, and the need for additional information.

There is an inconsistent body of knowledge regarding multiple-day trips on the Connecticut River. The PAD produced by the Licensee lists facilities that are not owned or operated by the Licensee, including commercial operations. There is a lack of consistency about those facilities in terms of their seasons of use and what amenities they provide for public recreational use and their long-term protection.

Several publications are widely used by paddlers and recreationalists. The primary source of information is *The Connecticut River Boating Guide: Source to Sea* (3rd ed.) published by the Connecticut River Watershed Council (2007). Recreational maps and guides to the river have been published for some reaches by KM Digital Productions in South Hadley, Mass., and are available from the Connecticut River Watershed Council. These foldout river maps cover the reaches from Vernon, Vt., to Turners Falls, Mass. (2008). Three other similar maps cover segments from Turners Falls (2007) down to Hartford, Conn. (2010), which is about the extent of the tidal zone. Most of those maps are in need of

updates. In 1991, New England Cartographics in Amherst, Mass., published the *Connecticut River Guide in Massachusetts* by Doug Greenfield and Christopher J. Ryan. The Connecticut River Birding Trail organization located in White River Junction, Vt., has published maps detailing the upper valley section, the northern section, and the southern section of the river.

The Connecticut River Paddlers' Trail prepared *The Connecticut River Paddlers' Trail MA-CT Expansion Feasibility Study* in 2013. In that document, Noah Pollock of the Vermont River Conservancy examined the Massachusetts and Connecticut reaches of the river. The *Connecticut River Paddlers' Trail MA-CT Expansion Feasibility Study* contained a map of the river in Massachusetts created by the Trust for Public Lands with dots indicating recommended locations for additional campsites. (See Appendix 1 attached.)

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The Turners Falls Dam prevents navigation downstream on the main stem of the Connecticut River. Project owners have a responsibility to the public to provide adequate portage trails and facilities that promote public recreation on the river, including access points and campgrounds with necessary amenities.

This study will be the defining mechanism for identifying additional sites that can best be adapted for increasing public access and multiple-day paddling trips on the Connecticut River. License requirements may include having the Licensees purchase additional property to provide camping, trail sites, portages or other facilities to assist the public.

The study may also identify indirect effects if the hydropower facilities and their projects have discouraged public use of the Connecticut River or displaced recreation to other parts of the watershed.

Cumulative effects also need to be studied because it appears that the number of dams on the river discourage multiple-day trips and have fragmented the recreational experience. This study may result in license requirements or other mitigation for the Licensee regarding multiple-day trips on the Connecticut River.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

Studies of the adequacy of public resources are fairly standard in the planning field. Methodologies can be selected from among the recognized and accepted standards of the resource and public planning fields. Surveys of people who do NOT use the river or are

displaced can employ randomized samples from several databases. Sufficient information is available from the guidebooks and maps of the river that identify access points and campsites, from the map done by the Paddlers' Trail for Massachusetts, as well as information contained in the PAD. The sites evaluated should be operated or funded by the licensee, not by others. Once a consultant is selected and approved, the information should be gathered and analyzed in a timely manner. The study would probably need a summer field season to locate river users for an adequate sample. A consultant with experience in similar projects should be selected, in part to create relevant comparisons to other hydropower projects around the country.

The AMC has some staff expertise in this area because it operates facilities in the White Mountains, in Maine, and elsewhere in its chapters. We could work with the Licensee or contractor to document the known information regarding the river. We will provide volunteers and technical support for the studies when possible as appropriate. We hope to work collaboratively with the Licensee on this study.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

There are several sites along the Connecticut River, private and public, that are used as access points or have camping facilities. However, vast differences exist in the ability or capacity of these sites to handle paddling groups with varying sizes or sanitation needs. Because there is no comprehensive guide or text that provides updated information, field inspection of existing sites should take place. Any needed reconstruction or rehabilitation of existing facilities should be identified. This analysis can be completed during any spring, summer, or fall field season. Such field research needs to be matched with projections of use in the future and with standard requirements for access sites, campsites, portages, sanitation facilities and other amenities. We know of no other means to obtain this information.

2. Controlled Whitewater Flow Study in the Bypass Reach below the Turners Falls Dam.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The Turners Falls project contains a 2.7-mile diversion that reduces in-stream flows in the natural riverbed except for minimum flow and during flood events. Natural boatable flows are frequently inaccessible, high, flashy, unpredictable, and are usually available only during periods of seasonal high spillage due to flooding. The Turners Falls Dam and diversion canal impacted the rapids below Turners Falls. The reservoir behind the dam almost certainly destroyed other rapids because it extends all the way north to the Vernon Dam.

Some of the whitewater opportunities eliminated by the project could be restored if the power company provided moderate, stable, and scheduled whitewater flows in the bypass reach that could be accessed from the late spring through early fall months. The current operation of the project largely eliminates valuable seasonal paddling opportunities.

Controlled flow studies have been done on dozens of FERC projects. This whitewater reach is a prime opportunity to restore a whitewater run that could be of enormous recreational and economic value to the community.

The goal of a whitewater flow study is to assess the presence, quality, access needs, flow information needs, and preferred flow ranges for river-based boating resources in a stepwise manner. The information to be obtained can be generally characterized as quantitative and qualitative descriptions of:

Turners Falls bypass reach with low flow, Feb. 1, 2013

- ∞ The range of optimal and acceptable flows for whitewater paddling in a whitewater park setting;
- ∞ The frequency, timing, duration and predictability of optimal and acceptable paddling flows under current conditions;
- ∞ The access needs of whitewater boating use and the current and potential river access options for paddling;
- ∞ The flow information needs of whitewater boating and the current and potential flow information distribution system;
- ∞ The location, challenge, and other recreational attributes associated with specific rapids and other river features.

Thus, the information to be obtained is a combination of user-generated flow preferences and other engineering information on current and proposed operations (e.g. discharges), geographic information and basic recreational information.

In simpler terms, the Turners Falls Dam would release prescribed flows into the bypass reach for this test, perhaps over two days. For each release, a selected group of paddlers would run the rapid and then answer written questions about their experiences at each flow level. The Turners Falls Dam would release several different flows, measured in cubic feet per second, and the paddlers' experiences would be analyzed to determine the flows that work best at the rapid.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

None of the three requesters is a resource agency.

The Commonwealth of Massachusetts owns and operates several river access areas on the Connecticut River in the vicinity of the Turners Falls Project, and thus has a clearly expressed interest in the public's ability to navigate the commonwealth's rivers. In addition, the Connecticut River and Watershed has been designated America's first National Blueway.

On May 24, 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. A Memorandum of Understanding signed in August 2012 by the departments of Interior, Agriculture, and the Army has as one objective "providing opportunities for scientific research, environmental education and outdoor recreation and access within the National Blueway to the extent compatible with agency missions." The National Blueway concept takes a watershed viewpoint and addresses the river from its source to the sea. The National Blueways System has as its goal "to advance a whole river and watershed-wide approach to conservation, outdoor recreation, education, and sustainable economic opportunities in the watersheds in which we live, work, and play." The National Blueway designation includes all the tributaries in the watershed and involves several federal and state agencies, including the U.S. Army Corps of Engineers, the Silvio Conte Refuge, U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration in the 7.2 million-acre Connecticut River Watershed.

The U. S. Fish & Wildlife Service (USF&W), National Marine Fisheries Service (NMFS) and the Massachusetts Department of Fisheries & Wildlife (MA-DF&W) have a clear interest in the passage of anadromous and other migratory fish including shad, blue-back herring, eels and other species through fish ladders at the Spillway, Station # 1 and Cabot. In addition, the Conte Anadromous Fish Laboratory is located within Project boundaries. Although the federal Atlantic Salmon Restoration Program has been recently curtailed, the above agencies continue to study and promote the effective upstream and downstream passage of many endangered or threatened species.

(3) If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

The Turners Falls bypass reach offers the public a high-quality whitewater boating resource when flow conditions are suitable. Conducting the necessary studies and implementing measures to ensure public access to outdoor recreation are in the public interest. It is widely accepted that outdoor recreation has significant benefits to participants including health, well being, and quality-of-life. Outdoor recreation also has proven economic benefits for communities located near recreational resources.

Aesthetic resources are also at play in the bypass reach. Dry riverbeds are ugly, and this one is in full view of many people who pass by on nearby Route 2 and who drive across the two Connecticut River bridges that enter the town of Turners Falls.

Turners Falls bypass reach with low flow, Feb. 1, 2013.

Restoration of whitewater recreational opportunities in the Connecticut River has the potential to offer the region economic benefits. FERC has concluded that *“to fully evaluate the project’s effect on whitewater recreation opportunities and to balance potential enhancement opportunities with their cost, a controlled-flow whitewater boating study is relevant to Commission’s public interest determination.”* This is equally true regarding the Turners Falls Project on the Connecticut River.

(4) Describe existing information concerning the subject of the study proposal, and need for additional information.

While many flow studies have been conducted during FERC relicensings on New England's rivers (e.g., Deerfield, Kennebec, Rapid, Green) that have a long history of whitewater paddling use, this section of the Connecticut River is largely unknown to whitewater boaters. Rapids are un-named, the range of difficulty is unknown, and current access opportunities are extremely difficult. The potential high quality of this scenic 2.7-mile long whitewater run should be explored.

Current and historic project operations, however, have resulted in significant information gaps and eliminate most of the low and moderate flows from this reach. The result has been flows too low to paddle, or flashy, spiking high flows that may be too dangerous to attempt. Intermediate paddlers, commercial paddlers, and general river-runners know relatively little about this river reach at low or moderate flows. It should also be determined if there is adequate potential to improve river access in a way that offers a high quality car-top put-in and take-out for use of the entire bypass reach.

One experienced paddler tested low water on the bypass reach in September 2012 to determine if it would be suitable for an office-outing float trip. She entered on river left below the Great Falls Discovery Center, and paddled around the bend. "The entry shallows gave way to a series of 2' high ledges, stacked upon each other," she wrote. "I chose a line more central to river right. I am not sure if there was rebar in them too, I just remember thinking it was too shallow to be in my playboat, and being extra careful not to flip. These would make for some fun rapids I think at higher water, as there was overall several feet of gradient change, and the rock was stacked and defined enough to possibly become something of whitewater significance." At the end of her test run, she concluded: "Regionally, the area lacks Class III rivers. The result is that it is difficult for many New England paddlers to make the transition from Class II to Class IV. With the reduction of the West River releases, and most other regional Class III rivers being spring runoff dependent, many of our regional paddlers will travel to other parts of the country to build their skills and step up to Class IV. Additionally in recent years, with less snow, and rain, dam releases on the Deerfield have come to define the extent of the paddling season. Once these have passed, paddlers find themselves searching for other activities to hold them through till the short season begins again. These include paddlers as far east as Boston, north as New Hampshire & Vermont, south as Connecticut, and Rhode Island, west as New York State. I am not sure if some of these river features might become Class III with more water, but if they could they would be an immense resource to regional clubs and training programs."

The use of a controlled-flow analysis has been described in Doug Whittaker, Bo Shelby, and John Gangemi, *Flows and Recreation: A guide to studies for river professionals* (2005), p. 26-29, available from the National Park Service website at:

<http://www.nps.gov/hydro/flowrec.pdf>

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The Project controls flows in the Connecticut River by withdrawing more than 13,000 cfs. The operations eliminate most of the paddling days each year, including the virtual elimination of valuable and regionally needed summer paddling opportunities. The Connecticut River can be a high-quality paddling resource, and since paddling is a flow dependent activity, the project directly affects paddling on the Connecticut River. The project nexus is direct.

The results of a controlled flow study would help determine the need for license requirements for scheduled whitewater releases.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The study we request on the Turners Falls bypass reach of the Connecticut River should follow the standard methodology as described in Whittaker, cited above. This methodology is designed to gather information to assess the presence, quality, and preferred flow ranges for river-based boating resources in a step-wise manner. The process steps are generally 1) desktop analyses, 2) on-land feasibility assessment, 3) on-water single flow assessment, 4) on-water multiple flow assessment. We expect and request the full implementation of this methodology.

Because the quality and flow needs of the resource are unknown, we request an on-water multiple flow assessment be conducted. This study will need to take place on various dates and at variable flow levels throughout a spring and summer. The Appalachian Mountain Club and other boating groups can work with the Licensee to document the known information regarding the river. Along with other paddling groups, we will help provide volunteer paddlers and technical support for the studies as appropriate. We hope to work collaboratively with the FirstLight on this study.

The whitewater boating study methodology we have requested has been used on dozens of other FERC regulated reaches. This study should include an examination of the access issues for the bypass reach and the take-out below.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

Representatives of the AMC and other NGOs with whitewater expertise are willing to work with the Licensee on the whitewater paddling controlled-flow study to keep costs reasonable and the quality of information high.

We will need the integration of information that is already known and then an organized flow study during which several flows are paddled by boaters, with still image and video

documentation, surveys of the boaters, a guided conversation among the boaters, and a written report. Given that this is a bypass reach with some minimal access and relatively straightforward hydrology, and given the collaborative approach sought by the paddling community, including in-kind contributions of time and expertise, a consultant should be able to complete this study on behalf of the Licensee for a very reasonable cost.

The Licensee PAD proposes no whitewater feasibility analysis. This no-action step will reveal nothing about the project impacts on whitewater recreation or opportunities for protection, mitigation, or enhancement measures. We currently do not know the relationship between specific low and moderate flows and the paddling experiences they provide. A desktop analysis cannot generate this information. Without this information we cannot fully define the project impacts, nor propose and consider provision of releases that provide targeted recreational experiences.

3: Cultural, Historical, and Educational Analysis and Recommendations.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The proper presentation and preservation of historical materials is particularly sensitive at Turners Falls. A major event in colonial America happened here in 1676. The Indian fishing village on the north side of the river was attacked by forces under Capt. William Turner. That battle site now lies mostly flooded under the Turners Falls reservoir. Indian burial grounds dating back thousands of years have been reported on or adjacent to project lands. Yet the Licensee does not have an educational program or interpretative signs that would allow visitors to understand that history.

A study should be done to determine a variety of options for educating the public about this historical site, and to determine what actions should (or should not) be taken to preserve artifacts and provide education.

Some people have suggested that a walkway be constructed on the northern or river right side with interpretative materials. Such a walkway could help solve other major issues with the dam, such as the lack of a portage pathway around the dam, and access to the bypass reach.

This study should also address a second issue. The engineers who built the dams at the Great Falls on the Connecticut River, now Turners Falls, were professionals who did excellent work. Part of that work included documenting their efforts in drawings, photographs (dating from as early as 1865), blueprints, inventories and plans. Those documents are now historical records that should be preserved for the public benefit. The study should discover what records remain and recommend plans for preserving them and making them available to historians and researchers.

We also have an interest in the educational opportunities for the public that should be provided by the project operators on the Connecticut River. Informational signage and kiosks at project facilities can and should promote education about invasive species, water flows, the history of the area, who to call with problems, and what to do to get involved. Existing data should be archived and be publicly accessible. These educational improvements should be coordinated with recreational improvements. These questions should be addressed in this study concerning the “proper presentation” and preservation of history.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

None of the three requesters is a resource agency. The tasks here are properly of concern to the state historical preservation agency and of such nearby institutions as the Great Falls Discovery Center in Turners Falls and the Pocumtuck Valley Memorial Association in Old Deerfield, Mass.

The study and presentation of information about the past involves Indian tribes. They were on one side in the 1676 battle, but more importantly they had lived at the site for centuries. An article titled “Bare Bones” in the *Greenfield Recorder* on Feb. 14, 2013, mentioned a development site near Turners Falls and said, “Sitting on the only lightly developed quadrant of the ancient Indian fishing site known as Peskeomskut (now Turners Falls dam), activists have attempted to derail development there for many years and reasons, including wetland and sacred burial-site issues. The activists claim the site was an important burial ground for local indigenous peoples dating back more than 10,000 years, and they say they have the bones to prove it.” The article by Gary Sanderson reported on an interview with an archeologist, George Nelson, who discovered what was presumably an Indian burial site in a sand bank being used for the reconstruction of Route 2 in 1964, including a full skeleton that he donated to the University of Massachusetts. In private correspondence, Sanderson said, “To be honest, everything within a mile radius of falls would have been loaded with ancient indigenous history/artifacts/burials. When widening Gill Road ca. 1860, they found a spoke burial, 12 bodies, the feet in the center separated by 10-foot circle, many beads, stones, possessions etc.”

In the PAD, the Licensee does not mention the 1676 battle, William Turner, or that the battlefield is submerged under the reservoir. In the PAD, the Licensee states that if any construction takes place the Massachusetts Historical Commission would likely require a Phase 1A study “given the sensitivity of archaeological resources within the given region.” Licensee also mentions that the Abenaki and the Narragansett tribes may be “potentially interested.” Since those tribes have been displaced from this region, perhaps they should be contacted.

(3) If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

Historical records and education are valuable public resources. The traditional Native American gathering at the fishing site across the river from Turners Falls is part of the collective heritage of Americans, as is the history of the 1676 battle.

The engineering records related to the construction of dams at Great Falls are also part of our social and industrial history. The first attempt at a Great Falls dam was in 1792, but it washed away. In 1865-66 a timber-crib dam was successfully constructed. It was drowned by a concrete dam in 1909-1912. In 1969-71, the current dam was constructed on the Gill side and the dam on the Turners Falls side was retrofitted with new gates. During that construction, the remains of the original timber-crib dam were removed.

Remnants of the 1865 timber-crib dam were revealed during construction in 1969-71. (Photo courtesy Ed Gregory archive.)

(4) Describe existing information concerning the subject of the study proposal, and need for additional information.

Many history books have dealt with the 1676 fight at Turners Falls and its ramifications during King Phillip's War. It remains unclear what historical resources remain under water and in the ground. Such sites have a chance of preservation under current laws. The question is: How can the operator of the Turners Falls Dam benefit the public through the presentation of the historical issues at the site?

A study could suggest various opportunities. Some people have suggested an interpretative trail could be cut along the riverbank on the north side with signs indicating the rich history of the area.

As for the engineering history of the site, several books have helped tell that story, but the records held by the Licensee have not been catalogued. Books that relate to this topic include Bill Gove, *Log Drives on the Connecticut River* (Littleton, N.H., Bondcliff Books, 2003), and Ed Gregory, *The Turners Falls Canal; History and Description* (2006).

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The reservoir at Turners Falls covers the site of the battle and probably a lot of artifacts. There may be Indian artifacts or burial grounds on Project lands. The nexus there is direct.

Concerning the colonial and ancient history around Turners Falls, FERC might require an educational component in the license requirements that could assist the public in understanding its history. This might be through direct Licensee action, such as the trail or displays mentioned above, and through support of the preservation of documents by institutions such as the Great Falls Discovery Center in Turners Falls or the Pocumtuck Valley Memorial Association in Old Deerfield.

Presumably the Licensee has in its possession scrapbooks, photographs, construction plans, blueprints, and other historical records related to the construction of the dam, or at least some surviving remnant of such documents. The nexus there is direct. Preservation of such documents should be a license requirement and they should be publicly accessible.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

In this case, tribal values and knowledge would be relevant in the case of Turners Falls.

The study methodology regarding interpreting Native American use of the area should be left to the tribes themselves, some of which are living locally or were long ago removed to Vermont, upstate New York, or Quebec, and to professional historians, anthropologists, and archeologists who are present in numbers at the University of Massachusetts, Amherst College, and the other regional institutions of higher education.

The Pocumtuck Valley Memorial Association, which operates the Memorial Hall Museum and Library located just downstream in Old Deerfield, Mass., has expertise in dealing with Native American artifacts, in creating museum displays, and in maintaining close contact with Native Americans in the region and in Canada. Its library contains

thousands of historical records of colonial America. (Deerfield was the site of another major historical battle on Feb. 29, 1704, when French and Indians came down from Canada and attacked Deerfield. They returned to Canada with more than 100 captives who, over time, were generally ransomed back to their families. Some, however, famously choose to live with the Indians. The Indians won that time.)

The generally accepted practices in historical preservation and museum presentation could lead to recommendations for license requirements.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

This area of Massachusetts is rich in academics and museum personnel who could contribute to the Turners Falls effort at a low cost compared to other studies. The people who are knowledgeable about archeology, anthropology, museum presentation, and history in the Turners Falls area are not all local, but some subset of them would be perfect for this study. We are not aware of any less-knowledgeable team that could do an adequate study and make recommendations.

Most of the work in locating the records owned by the Licensee would be internal, with advice and recommendations coming from professional historians after the scope and location of the documents is known. Study of educational opportunities would benefit from consultations with local outdoor educators and schools.

4: Recreation Study at Northfield Mountain.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

We request a study to recommend improvements and additions that would return the Northfield Mountain Recreation facility to its original intent during its initial licensing and to the level of public benefit required under the previous license. Additions should be recommended as appropriate for a new license. Options might include providing snowmaking for cross-country skiers, or buying additional lands to improve recreation.

There are important issues at Northfield Mountain concerning trails of national significance. The New England Scenic Trail (NET) runs through project lands at Northfield Mountain. The New England National Scenic Trail is a 215-mile trail in Connecticut and Massachusetts that received federal designation in 2009. FirstLight has agreed that a relocation of the NET within project boundaries would provide an enhanced recreational experience and level of safety for the public. This involves moving the trail at a greater distance from the storage reservoir at the mountaintop. Relocating the NET could improve access to popular climbing areas nearby. A recreational study could provide assistance in both cases, possibly by recommending that the Licensee buy nearby

land from willing sellers to preserve the climbing areas and provide the best route for the New England Trail.

Major improvements in boating could be required in a new license. FirstLight needs to provide more campsites and access points in the long reach of the Connecticut River that it controls. The Connecticut River Paddlers' Trail recommends one campsite for every five river miles with access in every community along the river. FirstLight's provision of such amenities has not reached that standard.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

None of the three requesters is a resource agency.

The Commonwealth of Massachusetts owns and operates several river access areas on the Connecticut River in the vicinity of the Turners Falls Project, and thus has a clearly expressed interest in the public's ability to recreate on the commonwealth's rivers. In addition to this interest, the Connecticut River and Watershed has been designated America's first National Blueway.

On May 24, 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. A Memorandum of Understanding signed in August 2012 by the departments of Interior, Agriculture, and the Army has as one objective "providing opportunities for scientific research, environmental education and outdoor recreation and access within the National Blueway to the extent compatible with agency missions." The National Blueway concept takes a watershed viewpoint and addresses the river from its source to the sea. The National Blueways System has as its goal "to advance a whole river and watershed-wide approach to conservation, outdoor recreation, education, and sustainable economic opportunities in the watersheds in which we live, work, and play." The National Blueway designation includes all the tributaries in the watershed and involves several federal and state agencies, including the U.S. Army Corps of Engineers, the Silvio Conte Refuge, U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration in the 7.2 million-acre Connecticut River Watershed.

(3) If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

The Turners Falls Recreation facility offers the public a high-quality resource when fully functional. Conducting the necessary studies and implementing measures to ensure that the facility delivers as promised is in the public access. It is widely accepted that outdoor recreation such as cross-country skiing, hiking, climbing, and boating have significant benefits to participants including health, well being, and quality-of-life. Outdoor recreation also has proven economic benefits for communities located near recreational resources.

(4) Describe existing information concerning the subject of the study proposal, and need for additional information.

The subject of recreation at Northfield Mountain has been addressed in several newspaper articles over the years. The study might examine expenditures by the Licensee over the years in support of the facility, its promotion, and usage.

The study might assess the adequacy of the facility. Launching a canoe on the river at the Northfield Mountain site is unattractive to paddlers, who are displaced to other facilities. Here's a passage that explains why from *The Connecticut River Boating Guide: Source to Sea* (3rd ed., 2007), p. 138, published by the Connecticut River Watershed Council:

Mile 124.5: You have now arrived at the **Riverview Picnic and Recreation Area** at **Northfield Mountain** on the left bank, which has a dock to accommodate the *Quinnetukut II* riverboat, offering river cruises for the general public (phone 800-859-2960). The Northfield Mountain pumped-storage generating plant is sheltered in the mountain behind the site. The main dock area must be kept clear for the *Quinnetukut II*, but boaters and paddlers may use the dock for brief stops to load and unload. The dock is inaccessible directly by car and can only be reached on foot from a parking area 100 yards away. Access is difficult, and the dock is unavailable from mid-April to mid-June. The power company stretches a fish net across the intake of Northfield Mountain during this time to prevent salmon smolt, which are heading downriver, from getting caught in the pumped-storage station. *Caution:* Avoid the discharge area marked by orange floats on the left bank, which can release enough water to swamp a small boat.

Additional information is needed that this study might produce. The study should assess the months of operation of the Riverview facility, which seems to open late and close early in the boating season. Sometimes the power company provides shuttle service for boaters doing day trips on the river, but apparently they charge for that service. The study should assess the appropriateness of such charges, and whether or not anything should be charged by a power company that uses the public's water as its fuel supply.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The Licensee operates the Northfield Mountain Recreation Area as partial mitigation for its operations at the Northfield Mountain Pumped-Storage Project. There is a direct impact on these resources.

The study should examine the skiing, snowshoeing, hiking, climbing, boating, sightseeing, and educational services provided by the facility with an eye toward how the

facility has met previous license requirements and how mitigation should be enhanced for a new license. The study could recommend ways that the facility could be updated and improved as the Licensee seeks a new federal license, and what conditions might be included in that license. The study and the license requirements should address needs for the 30-year proposed life of the license.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The study might make use of several techniques to determine the effectiveness of the Northfield Mountain recreation facilities. Surveys could determine issues that are current in the skiing, climbing, boating and hiking communities. A survey might also seek to determine what discourages the public from using the facility, or displaces recreation to other areas in the watershed. Such studies have been developed in the administration of parks and recreation areas and can be adapted to this task.

During the relicensing process, there should be plenty of time to collect and analyze data for this task, which would need a full year in order to have access to year-round recreationists.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

The Appalachian Mountain Club has some expertise in this area through its operation of trails and huts in the White Mountains and along the Appalachian Trail in Maine. We are willing to work with the Licensee on the study to keep costs reasonable and the quality of information high. Given such in-kind contributions of time and expertise, a consultant should be able to complete this study on behalf of the Licensee for a very reasonable cost.

The Licensee PAD proposes no recreation analysis of this sort. This no-action step will reveal nothing about the project impacts on recreation or opportunities for mitigation or enhancement measures. Without this information, we cannot fully define the project impacts, nor propose and consider provision of license requirements to improve recreational experiences.

5. Study of the Economic Health of Ownership and Creation of a Decommissioning or Trust Fund.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

We request a study on the creation of a decommissioning fund or trust fund to protect the public interest. New England's rivers are littered with abandoned dams. Over the centuries, companies have failed, and weather events or human error have crippled dams that were then simply left behind. Energy markets and ownerships have been changing quickly.

A "perfect storm" event, might breach a dam such as Turners Falls. Most of the Connecticut River dams are elderly facilities. The Turners Falls portion of this dam dates from 1909 while the Gill side of the dam dates from 1965.

Distant events, changing regulations, new energy sources, currency devaluations or unfortunate weather events could compromise the health of the current project. If something happened, the public should be insured against the burden of decommissioning costs. A study should recommend the terms of a license requirement for a decommissioning fund.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;

We are unaware of the resource agencies' jurisdiction over decommissioning funds.

(3) If the requester is a not resource agency, explain any relevant public interest considerations in regard to the proposed study.

The economic security of a federally licensed hydropower dam on the longest river in New England is clearly in the public interest. Many hydropower projects support robust recreation economies and they produce a public good by generating renewable forms of electricity.

But the historical record demonstrates—by the thousands of abandoned dams on New England's rivers—that the public should not accept the burden of industrial failure any longer. It has become common to create decommissioning funds at such federally licensed facilities as a way of insuring the public interest against having to pay for removal of a damaged facility or to take over from a failed corporation.

(4) Describe existing information concerning the subject of the study proposal, and the need for additional information.

We are unaware of any published information on the economic viability of the individual dams, which may need to be studied under a non-disclosure agreement, or of the performance of decommissioning funds or other trust funds for this purpose.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

There is a direct connection between Project operations and the economic viability of each individual dam. Study results could lead to a license requirement setting up an escrowed decommissioning or trust fund to protect the public interest.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The financial viability portion of the study would follow normal procedures in accounting and financial management. The rules of trusts or decommissioning funds are well known.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

The requested study would be relatively inexpensive. Funding the trust would be another matter. We are unaware of alternative means of securing the public from risks that the corporations or the physical assets might fail during the course of the federal license.

Conclusion:

We respectively request studies of multiple-day self-powered trips on the river, a controlled-flow analysis in the bypass reach; a historical, educational, and cultural study; a recreation study at Northfield Mountain; and a decommissioning study that will support dialog and analysis regarding the relicensing of the Turners Falls Dam and the Northfield Mountain Pumped Storage facility.

In addition, we offer our comments on the PADs to better inform this relicensing process. Thank you for considering these comments.

Respectfully submitted this 28th day of February, 2013.

PROCESS, AND SCOPING: REQUEST FOR COMMENTS ON THE PAD AND SCOPING
DOCUMENT, AND IDENTIFICATION OF ISSUES AND ASSOCIATED STUDY
REQUESTS REGARDING THE TURNERS FALLS HYDROELECTRIC PROJECT, FERC
PROJECT NO.1889-081 AND THE NORTHFIELD MOUNTAIN PUMP STORAGE
PROJECT, FERC PROJECT NO. 2485-063.**

New England FLOW is a regional non-profit organization whose affiliations have represented whitewater boaters, canoeists, rafters, and other river users on multiple project re-licensings throughout New England for over 25 years. American Whitewater is a national non-profit organization dedicated to protecting and restoring our nation's whitewater resources and enhancing opportunities to enjoy them safely. Since 1876, the Appalachian Mountain Club (AMC) has promoted the protection, enjoyment, and understanding of the mountains, forests, waters, and trails of the Appalachian region, and is the largest conservation and recreation organization in the Northeast with more than 90,000 members. All three groups are steering committee members of the Hydropower Reform Coalition based in Washington, D. C. Our members who are primarily conservation-oriented kayakers, canoeists, and rafters would enjoy this section of the Connecticut River as a weekend trip.

The Turners Falls section of the Connecticut River has the potential ability to offer whitewater paddling opportunities of sufficient quality during irregular spillage events. At moderate spillage flows, the bypass run is used by boaters to surf waves and perform a wide array of acrobatic tricks called "freestyle" paddling. All manufacturers of whitewater kayaks design boats for this purpose.

In addition to kayaking, this reach has potential for rafting, guided kayaking, canoeing, instruction, and general paddling use. Collectively, the recreational use of the resources at this project has the potential to add economic value to the region given its central New England location and its proximity to the University of Massachusetts, Holyoke and Greenfield Community Colleges, and the Northfield-Mt. Hermon School. Millions of people live within a three-hour drive of the Turners Falls facility.

Issue #1: Impacts of the Connecticut River flow diversion on recreational paddling at the Turners Falls bypass reach.

The Turners Falls project's 2.7-mile diversion reduces instream flows substantially, leaving only minimum flows or those flows required for fish passage by the U. S. Fish & Wildlife Service, National Marine Fisheries Service, or the Massachusetts Department of Fish & Wildlife. Natural boatable flows under current operations are high, flashy, unpredictable, and are only available during periods of seasonal spillage to reduce flooding. Some of the whitewater opportunities eliminated by the project could be provided in a moderate, stable, and predictable operational mode and occur during warm weather. The current operation of the project, and lack of access, virtually eliminates valuable summer paddling opportunities.

Lost Rapids Below the Dam Under Turners Falls Bridge

The analysis presented is based on the anecdotal experience provided by local and regional boaters who have used this reach when it becomes available. The recreation-flow relationship needs to be substantiated through both operational analyses and recreational analyses. The correct context to conduct this inquiry is through the use of a “controlled-flow analysis,” a stepwise methodology described by Whittaker et al., in *“Flows and Recreation: A guide to studies for river professionals”* (2005), as we formally request below.

In the PAD, the Licensee proposes no flow enhancement to mitigate the project's effects on whitewater recreational use.

In addition to recreation and aesthetics, we recognize that flow-related decisions also affect economic factors related to power generation and other environmental variables, particularly fish passage. We look forward to exploring how all flow-related values relate to one another through participation in this relicensing process.

Issue # 2: Public Access for whitewater boating, rafting, and canoeing is inadequate.

Directly below the Turners Falls Dam at Station #1, there is currently no formal public access or parking owned by the Licensee for whitewater boaters. In order to access the whitewater rapids directly below the Turners Falls Dam, boaters must use the parking available at the Great Falls Discovery Center. Adjacent to the Center is a footpath that boaters can traverse down to the river; however, the Licensee does not own this lot. For access to the whitewater flows below the Cabot Station, parking for boaters is likewise problematic, with limited parking. The takeout for both runs (Station # 1 and Cabot) is at the confluence of the Deerfield River. The access road to this site is not adequate for ordinary 2-wheel drive vehicles and should be upgraded. The steep riverbanks make egress at the end of the run difficult, and although able-bodied kayakers can struggle up the path, the terrain severely limits rafting use, or use by anyone carrying a heavy canoe.

The Licensee identifies in the PAD a shuttle service around the dam for canoeists or boaters, but it provides no value to whitewater enthusiasts who wish to access the rapids immediately below the dam. Boaters are picked up at Barton Cove and shuttled to a put-in off Poplar Street in Montague City, eliminating any potential whitewater run. This portage is unacceptable for flatwater boaters and no use at all to whitewater boaters.

In the PAD, the Licensee proposes no new river access areas.

Issue # 3: Adequacy of camping and sanitary facilities available for multiple-day kayaking or canoe trips (Recreation Use and Needs).

In the PAD, the Licensee cites the Massachusetts SCORP (2006-2011), which indicated a need for “water-based” activities, and one of the goals of the New Hampshire SCORP identified the need for a variety of recreational opportunities. The Vermont SCORP (2005-2009) reveals the need for access to all types of outdoor recreation. While the applicant has itemized and described the different recreational opportunities available throughout the reach from Turners Falls Dam to the Vernon Dam, they have not provided a qualitative analysis of these facilities.

Information provided by canoe clubs and other river recreational interests cite changing demographics and an increase in sea kayaking as reasons for the high interest in flatwater paddling and multiple-day canoe trips.

In the PAD, the Licensee identifies two sites, Barton Cove Campground and Munn’s Ferry Campground, as the only two sites with facilities amenable to multi-day trips. However it does not quantify the number of campsites available or the quality of the facilities within each location. Barton Cove Campground does not have a suitable landing site. Nor does the PAD address the adequacy of such facilities for increased use over the next 30 years of a license.

In the PAD, the Licensee proposes no new camping sites or upgrades to existing sites.

Issue #4: Economic impacts.

The diversion of flow around the Turners Falls Dam has significant negative recreational impacts and related socio-economic impacts. By changing the operational scenario of the Turners Falls Project, the potential exists to create new tourism products for a region that is primed to capitalize on it. Retail activity, and food and lodging opportunities will be geared toward non-commercial paddlers, and thousands of people who currently travel to the region each year for rafting, kayaking and other outdoor adventure activities will discover added value to the region.

In making a public interest decision, FERC must weigh the value of water in the river against the value of water in the bypass reach, and then reach a comprehensive plan for the development of the river that strikes the appropriate balance and is best adapted to the river. In many dam relicensing proceedings, the values of flow restoration are largely recreational and ecological, and thus hard to evaluate in dollars. In this case, because of its potential to increase recreation with scheduled flows, we believe FERC should also weigh the predicted economic value associated with the recreational use when looking at various alternatives.

Issue #5: Mitigation for Loss of Whitewater Recreation at Great Falls and Upstream

The Turners Falls Dam sits atop Great Falls and drowns whitewater rapids upstream under a reservoir that extends all the way to the Vernon Dam. Construction of the dam eliminated significant whitewater opportunities both above and below the dam. It would be possible to compensate for this loss through either on-site or off-site mitigation such as at Bellows Falls.

Lost Rapids in the Bypass Reach Below the Dam

In 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. The National Blueway System (NBS) goals include

providing outdoor recreation. NBS takes a watershed and source-to-the sea view of the river in seeking to advance “conservation, outdoor recreation, education, and sustainable economic opportunities” in the watershed. The National Blueway designation includes all the tributaries in the 7.2 million acre Connecticut River watershed and has the support of several federal agencies, including the U.S. Army Corps of Engineers, the Silvio Conte Refuge, U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration.

Study Requests

We hereby request several studies per 18 CFR 5.9(b).

1. Controlled Whitewater Flow Study in the bypass reach below Turners Falls Dam.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of a whitewater flow study is to assess the presence, quality, access needs, flow information needs, and preferred flow ranges for river-based boating resources in a stepwise manner. The information to be obtained can be generally characterized as quantitative and qualitative descriptions of:

- The range of optimal and acceptable flows for whitewater paddling;
- The frequency, timing, duration and predictability of optimal and acceptable paddling flows under current conditions in the bypass reach, and how proposed alternative operations could be used;
- The access needs of whitewater boaters and the current and potential river access option for whitewater and other paddling;
- The flow information needs of whitewater boating and the current and potential flow information distribution system;
- The location, challenge, and other recreational attributes associated with specific rapids and other river features.

Thus, the information to be obtained for the whitewater paddling study is a combination of user-generated flow preferences and other data from test runs, information on current and proposed operations (e.g. discharges), geographic information, and basic recreational information.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

The requester is not a resource agency.

(3) If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

The Turners Falls bypass reach offers the public a high-quality whitewater boating resource when flow conditions are suitable. Conducting the necessary studies and implementing measures to ensure public access to outdoor recreation is in the public interest. It is widely accepted that outdoor recreation has significant benefits to participants including health, well being, and quality-of-life. Outdoor recreation also has proven economic benefits for communities located near recreational resources.

Restoration of whitewater recreational opportunities in the Connecticut River has the potential to offer the region economic benefits. FERC has concluded that *“to fully evaluate the project’s effect on whitewater recreation opportunities and to balance potential enhancement opportunities with their cost, a controlled-flow whitewater boating study is relevant to Commission’s public interest determination.”* This is equally true regarding the Turners Falls Project on the Connecticut River.

The Commonwealth of Massachusetts owns and operates several river access areas on the Connecticut River in the vicinity of the Project, and thus has a clearly expressed interest in the public’s ability to navigate the state’s rivers. In addition to this interest, the Connecticut River and Watershed has been designated at America’s first *“Heritage River”* and *“National Blueway.”*

(4) Describe existing information concerning the subject of the study proposal, and need for additional information.

While many flow studies as described above have been conducted during FERC relicensings on New England’s rivers (e.g., Deerfield, Kennebec, Rapid, Green) that have a long history of whitewater paddling use, this section of the Connecticut River is largely unknown to whitewater boaters. Rapids are un-named, the range of difficulty is unknown, and current access opportunities are difficult. The potential high quality of this scenic 2.7-mile long whitewater run should be explored.

Current and historic project operations, however, have resulted in significant information gaps and virtually eliminate all stable low and moderate flows from this reach. The result has been flows too low to paddle, or flashy, spiking high flows. Intermediate paddlers, commercial paddlers, and general river-runners know relatively little about this river at low or moderate flows. It should also be determined if there is adequate potential to improve river access in a way that offers a high quality car-top put-in and takeout that allows for use of the entire bypass reach.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The Project controls flows in the Connecticut River by withdrawing more than 13,000 cfs. The operations eliminate 95% of the paddling days on average each year, including the virtual elimination of valuable and regionally needed summer paddling opportunities. The Connecticut

River can be a high-quality paddling resource, and since paddling is a flow dependent activity, the project directly affects paddling on the Connecticut River. The project nexus is direct. The results of a controlled flow study would help determine the need for license requirements for scheduled whitewater releases.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The study we request on the Turners Falls reach of the Connecticut River should follow the standard methodology as described in Whittaker, referenced above. This methodology is designed to gather information to assess the presence, quality, and preferred flow ranges for river-based boating resources in a step-wise manner. The process steps are generally 1) desktop analyses, 2) on-land feasibility assessment, 3) on-water single flow assessment, and 4) on-water multiple flow assessment. We request the full implementation of this methodology.

Because the quality of the resource and flow needs are not known, we request that an on-water multiple flow assessment be conducted. This study will need to take place on various dates and at variable flow levels throughout a spring and summer. Spring dates are needed to capture moderate and high flows, which may be primarily stochastic, while late spring and summer dates afford the opportunity for scheduled lower flow releases. Higher flow data may be best gathered by an internet-based survey, while lower flow data may be best gathered on-site through controlled study opportunities. We will work with the Licensee to document the known information regarding the river. We will provide volunteers and technical support for the studies as appropriate. We hope to work collaboratively with the Licensee on this study. The whitewater boating study methodology we have requested has been used on dozens of other FERC regulated reaches.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

We are willing to work with the Licensee on the whitewater paddling controlled-flow study to keep costs reasonable and the quality of information high. The information that is already known can jump-start the study process and avoid un-needed effort. What will be subsequently needed is the integration of this information and then an organized flow study during which several flows are paddled by boaters, with still image and video documentation, surveys of the boaters, a guided conversation among the boaters, and subsequently a written report. Given that this is a bypass reach with some access and relatively straightforward hydrology, and given the collaborative approach sought by the paddling community, including in-kind contributions of time and expertise, a consultant should be able to complete this study on behalf of the Licensee for a very reasonable cost.

The Licensee PAD proposes no whitewater feasibility analysis. This no-action step will reveal nothing about the project impacts on whitewater recreation or opportunities for protection, mitigation, or enhancement measures. We currently do not know the relationship between

specific low- and moderate-flows and the paddling experiences they provide. A desktop analysis cannot generate this information. Without this information we cannot fully define the project impacts, nor propose and consider provision of releases that provide targeted recreational experiences.

2. Public Access for whitewater boating, rafting, and canoeing is inadequate.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of this study is to identify and define adequate access points that provide trails and car-top parking at Station #1 and Cabot Station, and egress at the end of the 2.7-mile run at the confluence of the Deerfield River. The paddling community is interested in access points for the following areas:

- At Turners Falls Dam at Station #1
- At Turners Falls Dam at the Great Falls Discovery Center
- At Cabot Station
- At the confluence of Connecticut and Deerfield Rivers.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;

The requester is not a resource agency.

(3) If the requester is a not resource agency, explain any relevant public interest considerations in regard to the proposed study.

The public has an interest in healthy rivers and streams that support the full suite of beneficial uses and other goals of the Clean Water Act. Access to streams and rivers with adequate base flows and sufficient variability to support high-quality whitewater recreational use will support other businesses within the regional economy.

Several federal agencies may have management goals under the National Blueway System, including the Department of Interior and the National Park Service.

(4) Describe existing information concerning the subject of the study proposal, and the need for additional information.

There is an inconsistent body of knowledge regarding access needs in this reach, and we look forward to learning more. The PAD does not identify access points for any type of whitewater use.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements

The project eliminates or does not provide access points for whitewater use. This study is vital to developing a mechanism for defining access points that can best be adapted for whitewater boating and other potential uses.

This study may result in license requirements or other mitigation for the Licensee regarding access to the Connecticut River.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The flows that paddlers enjoy on virtually all undammed streams are natural components that provide recreation and multiple other functions. Hydropower project operations disrupt or eliminate access that would otherwise naturally provide these recreational values. We request sufficient analysis be conducted to understand the Project topography that would detail which sites would best provide adequate access for multiple uses. Use of Geographic Information System (GIS) may provide a general overview of potential access points within Project bounds and may be helpful.

Given the steep topography leading to the bypass reach, this work should be completed using accepted and certified surveying methods that “ground truth” GIS analysis. Scheduling of this work should be completed during the summer field season when low seasonal flow will allow surveying activities within the bypass reach.

Boater access ramp at the Kennebec River in Maine

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

The recommended GIS analysis is a relatively simple desktop analysis using software that is currently available and thus should require little effort or cost. Once potential access points are identified, the cost of a survey is nominal when presented in the context of other studies required by FERC or other stakeholders. No other studies would address the specificity required to identify, layout, and design adequate access for this project.

3: Camping and sanitary facilities available for multiple-day kayaking or canoe trips (Recreation Use and Needs).

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of this study is to provide a quantitative and qualitative analysis of existing facilities to determine their capacity to manage the increasing number of paddlers who are making multiple-day trips on the Connecticut River. This study should also identify other points on the river that would be suitable for the establishment of additional facilities. And it should assess the adequacy of such facilities for a 30-50 year license period during which river use will increase dramatically.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied;

The requester is a not resource agency.

(3) If the requester is a not resource agency, explain any relevant public interest considerations in regard to the proposed study.

The public has an interest in healthy rivers and streams that support the full suite of beneficial uses and other goals of the Clean Water Act. Access to streams and rivers with adequate base flows and sufficient variability will support high-quality recreational use. Information provided by canoe clubs and other river recreational interests cite changing demographics and the rise of sea kayaking as reasons for high interest in flatwater paddling and multiple-day canoe trips.

In the PAD, the Licensee cites the Massachusetts SCORP (2006-2011), which indicated a need for “water-based” activities, and one of the goals of the New Hampshire SCORP identified the need for a variety of recreational opportunities. The Vermont SCORP (2005-2009) reveals the need for access to all types of outdoor recreation.

In addition, the National Blueway System seeks to promote recreational uses wherever possible.

(4) Describe existing information concerning the subject of the study proposal, and the need for additional information.

The Licensee identifies two sites, Barton Cove Campground and Munn’s Ferry Campground, as the only two sites with facilities amenable to multi-day trips. One of the better publications available to gather this information is *The Connecticut River Boating Guide: Source to the Sea*, published by the Connecticut River Watershed Council, 3rd Edition, 2007. Those who have through-paddled the Connecticut River say that camping opportunities evaporate once they cross the Massachusetts border. They find islands closed to camping, and frequently end up sleeping on mudflats or illegally camping on isolated privately-owned sites.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

This study will be the defining mechanism for identifying additional sites that can best be adapted for increasing public access and multiple-day paddling trips on the Connecticut River. License requirements may include having the Licensee purchase additional property to provide camping, trail sites, portages or other facilities to assist the public.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

Our interest is in having sufficient information to understand what facilities exist, and what, if any, improvements are necessary to manage an increasing use of multiple-day kayak and canoe trips on the Connecticut River. This analysis should include recommendations for the acquisition and development of additional facilities to meet the interests and needs identified in the multi-state SCORP documents cited by the Licensee in the PAD, and adequate for a 30-50 year license.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

There are several sites along the Connecticut River, private and public, that are used as access points or have camping facilities. However, there are vast differences in the ability or capacity of these sites to handle paddling groups of varying size and numbers or sanitation needs. Because there is no comprehensive guide or text that provides updated information, visual inspection of existing sites should take place. Any needed reconstruction or rehabilitation of existing facilities should be identified. This analysis can be completed during any spring, summer, or fall field season. Such field research needs to be matched with projections of use in the future and with standard requirements for access sites, campsites, portages, and sanitation facilities.

4: Economic impacts.

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of the recreational economic impact study is to examine the regional economic benefits of various flow alternatives that can be provided by restoring flows to the Turners Falls bypass reach. This study should include a contingent valuation study that compares the economic values of recreation to power generation.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

The requester is not a resource agency.

(3) If the requester is a not resource agency, explain any relevant public interest considerations in regard to the proposed study.

Economic stimulus is clearly in the public interest. Many New England hydropower projects support robust recreation economies. The Deerfield River (FERC No. 2334-0-0) currently injects over \$10 million annually into the community of Charlemont, Massachusetts, and is a superb example of supporting multiple businesses throughout the town. Other examples include the Kennebec River and the Penobscot River in Maine, the Black River in New York, and the Gauley River in West Virginia.

(4) Describe existing information concerning the subject of the study proposal, and the need for additional information.

We are unaware of existing information regarding the economic potential of the Turners Falls bypass reach and we look forward to learning more. However, Crane Associates of Burlington, Vermont, published a study in 2005: *“The Economic Impacts of Whitewater Boating on the West River, Jamaica, Vermont.”*

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The project has eliminated most paddling opportunities throughout the year. Many of these days could provide kayaking, instructional paddling, canoeing, paddle-boarding, and rafting, all of which have ancillary economic benefits associated with any form of tourism.

Understanding the economic values that could be provided by restoring paddling recreation to the Turners Falls bypass reach will assist FERC and other stakeholder in balancing the trade-offs associated with lost generation. In the case of the Deerfield River, the value of whitewater recreation outweighed the value of power generation by a margin of 24:1.

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

Since the present economic values cannot be determined because there is currently minimal recreational activity in the bypass reach, we request the study be compiled using the *“contingent valuation”* method that measures individual’s *“willingness to pay.”* These values can then be compared to the dollar values of power generation. The economic benefits can be extrapolated to develop an understanding of how those dollars will be multiplied throughout the community as benefits associated with paddling activities. Overall visitor spending will contribute to the

economy of the immediate and adjacent region. Such a contingent valuation study would appropriately be done following test runs on the bypass reach for the study described above.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

Primary data should be collected through survey instruments circulated through known paddling clubs throughout New England during the winter months. Individual interviews should be taken on days when the nearby Deerfield River is having releases, and the survey should include kayakers, canoeists, and rafters of varying abilities. Customers of commercial outfitters should also participate in the survey as well as outfitters that provide tubing equipment for those individuals that enjoy just floating down the river. Paddlers who participate in test runs would have a firsthand knowledge of the values.

Contingent valuation studies provide reliable, comparable information that can be used to frame license requirements.

The Licensee has proposed no economic studies in the PAD.

5. Mitigation of Impacts on the Connecticut River and Loss of Whitewater Recreation at and above Turners Falls Dam

(1) Describe the goals and objectives of each study proposal and the information to be obtained.

The goal of this study is to assess the presence, quality, access needs, flow information needs, and preferred flow ranges for regional whitewater boating resources that would mitigate for the loss of whitewater recreation at the Turners Falls Dam.

(2) If applicable, explain the relevant resource management goals of the agencies or Indian tribes with jurisdiction over the resource to be studied.

The requester is not a resource agency.

(3) If the requester is not a resource agency, explain any relevant public interest considerations in regard to the proposed study.

The Turners Falls Dam removes the public's opportunity to enjoy a whitewater boating resource. Conducting studies and implementing the necessary measures to ensure the public has access to whitewater recreational resources is in the public interest.

Using off-site mitigation has historically been an acceptable practice in FERC licensing. This is evidenced in the Upper Androscoggin Settlement Agreement (FERC No. 11834-000) for the Rapid and Magalloway Rivers in Maine, as well as the Canada Falls Settlement Agreement (FERC No. 2634) for the South Branch of the Penobscot River in Maine.

On May 24, 2012, Secretary of the Interior Ken Salazar designated the Connecticut River and Watershed as the nation's first National Blueway. A Memorandum of Understanding signed in August by the Departments of Interior, Agriculture, and the Army has an objective of "providing opportunities for scientific research, environmental education and outdoor recreation and access within the National Blueway to the extent compatible with agency missions." The National Blueway concept takes a watershed viewpoint and addresses the river from its source to the sea. The National Blueways System has as its goal "to advance a whole river and watershed-wide approach to conservation, outdoor recreation, education, and sustainable economic opportunities in the watersheds in which we live, work, and play." The National Blueway designation includes all the tributaries in the watershed and involves several federal agencies. These agencies include the U.S. Army Corps of Engineers, the Silvio Conte Refuge, the U.S. Fish and Wildlife Service, the National Park Service, and the States of Connecticut, Vermont, New Hampshire, and the Commonwealth of Massachusetts, which have prioritized conservation, recreation, and restoration in the 7.2 million-acre Connecticut River Watershed.

Restoration of recreation opportunities in the watershed of the Connecticut River has the potential to offer the region significant economic benefits.

(4) Describe existing information concerning the subject of the study proposal, and need for additional information.

Current and historic project operations at the Turners Falls Dam provide no consistent or meaningful information for this type of mitigation. It should be determined what flows in the region are best suited for maximum recreational use.

(5) Explain any nexus between Project operations and effects (direct, indirect, and/or cumulative) on the resource to be studied, and how the study results would inform the development of license requirements.

The flows from Station #1 and Cabot Station at Turners Falls vary between base load and peaking. It becomes very difficult for whitewater boaters to have any consistent flows for whitewater recreation. The Project controls the entire flow in the Connecticut River and the Licensee apparently has limiting factors that generally prevent boatable conditions in the bypass reach and main stem channel except during flood conditions. The result also damages regionally needed summer paddling opportunities in the main stem below the bypass reach.

The dam itself was built on the Great Falls and dewatered the bypass reach, and the reservoir drowned upstream rapids, which would be sufficient cause for off-site mitigation. FERC needs to balance the paddling resources and power generation under the "*Electric Consumers Protection Act*" (16 U.S. C. §797,803). The project nexus is direct.

Study results would and should develop the basis of license terms, including possible off-site mitigation, that could protect the public interest and provide the balance mandated under ECPA.

Lost Rapids Downstream From Station #1 and Cabot Station

(6) Explain how any proposed study methodology (including any preferred data collection and analysis techniques, or objectively quantified information, and a schedule including appropriate field season(s) and the duration) is consistent with generally accepted practice in the scientific community or, as appropriate, considers relevant tribal values and knowledge.

The first step would gather information to assess the presence and quality of options for off-site mitigation. The process steps are generally 1) desktop analyses of candidate rivers, 2) resource agency identification and feasibility assessment, and 3) inter-agency meetings with resource agencies, Licensee, and representatives of the boating community to explore opportunities for mitigation.

We will provide volunteers and technical support for the studies as appropriate. We hope to work collaboratively with the licensee and other agencies on this study.

(7) Describe considerations of level of effort and cost, as applicable, and why any proposed alternative studies would not be sufficient to meet the stated information needs.

We are willing to work with the Licensee on an off-site mitigation study to keep costs reasonable and the quality of information high. Any information that is already known through numerous guidebooks and publications can jump-start the study process and avoid un-needed effort. What will be subsequently needed is the integration of this information and then organized meetings to study alternatives, and subsequently a written report.

Given the collaborative approach sought by the paddling community, including in-kind contributions of time and expertise, the Licensee and agencies should be able to complete these studies for this unique approach to mitigation for a very reasonable cost.

The Licensee PAD proposes no whitewater feasibility analysis.

Conclusion:

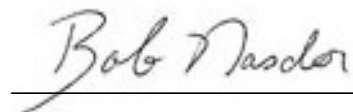

We respectfully request the hydrological, recreational, economic studies, and off-site mitigation that will support the dialog and analysis regarding the restoration of flows and associated recreational values to the Turners Fall project.

In addition, in these comments we offer our comments on the PAD, to better inform this relicensing process. Thank you for considering these comments.

Washington, DC 20426

Subject: Comments on Scoping Document 1 for the Wilder (FERC No. 1892-026), Bellows Falls (FERC No. 1855-045), Vernon (FERC No. 1904-073), and Turners Falls (FERC No. 1889-081) hydroelectric projects, and the Northfield Mountain Pumped Storage Project (FERC No. 2485-063)

Dear Secretary Bose:

I am writing this letter as the University Director of the Northeast Climate Science Center. This letter is in response to the December 21, 2012 Federal Energy Regulatory Commission (FERC) filing of the Notice of Intent to File License Application, Filing of Pre-Application Document (PAD), Commencement of Pre-Filing Process, and Scoping; Request for Comments on the PAD and Scoping Document, and Identification of Issues and Associated Study Requests for the Wilder, Bellows Falls, Vernon, and Turners Falls hydroelectric projects, and the Northfield Mountain Pumped Storage Project.

The Northeast Climate Science Center (NECSC) is one of eight of the Department of Interior (DOI) funded Climate Science Centers, which are supported by the US Geological Survey's National Climate Change and Wildlife Science Center (NCCWSC). The national mission of the NCCWSC is to provide natural resource managers with the tools and information they need to develop and execute management strategies that address the impacts of climate and other ongoing global changes on fish and wildlife and their habitats. The three primary goals of the NCCWSC are to: 1) Assess and synthesize our state of knowledge about climate change impacts, 2) Work collaboratively with the resource management community to develop adaptation methodologies that minimize the effect of climate change impacts on the Nation's fish, wildlife, and habitats, and 3) Foster research that increases understanding of the interactions between climate and the physical, biological, and chemical forces that influence the structure and functioning of ecosystems and the goods and services they provide.

The Northeast Climate Science Center was established one year ago, and received its initial funding from DOI for a five year period. The NECSC is composed of a consortium of universities comprised of the University of Massachusetts Amherst, College of Menominee Nation, Columbia University, Marine Biological Laboratory, University of Minnesota, University of Missouri-Columbia, and University of Wisconsin-Madison. As one of eight

Climate Science Centers, our study area is the greater northeastern portion of the US. This region is contained within boundaries ranging from Maine southward to Virginia, westward to Missouri, then northward to Wisconsin, and the eastward back to Maine. This area is a region of enormous diversity in geography, climate, biology, and human land use. The NECSC serves 22 states, multiple ecoregions, seven of the 21 regions established for the National Landscape Conservation Cooperative (LCC) Program, and a human population of 131,000,000 (41% of the US population). One of our goals is to understand the impacts of climate change on the resources in this region. In particular, we are very interested in the interface between climate change, infrastructure and natural resource management.

The FERC relicensing of the reservoirs on the Connecticut River is a very important process and I have been following it with great interest. I have been extremely impressed with the level of engagement demonstrated by the natural resource community and the excellent work by the FERC staff. I am writing to add the voice of the NECSC to those who have expressed concerns that in this process, the impacts of climate change on the streamflows in the Connecticut River be explicitly considered in evaluating management alternatives and options.

During the last five years, researchers at the University of Massachusetts Amherst have been studying the range of impacts of climate change on the Connecticut River. We have done this using the hydrologic models of the Connecticut River basin, outputs from highly regarded General Circulation Models (GCMs) and likely emission scenarios provided by the Intergovernmental Panel on Climate Change (IPCC). These results provide a range of future possibilities; however, they consistently indicate the following: 1) An increase in annual temperatures, 2) An increase in total annual precipitation, 3) An increase in high flow events, 4) Significant shifts in the timing of the annual hydrograph, and 5) Greater variability in the low flow regime.

All of these changes can have significant impacts on the flows in the Connecticut River and on how the hydropower facilities on the river and its tributaries should be managed. The relicensing process led by FERC is the one opportunity that exists to investigate how these climate change impacts may influence reservoir operations, and in turn, the management of the aquatic resources in the river.

There is no doubt that climate change is real, that, nationally, we are already seeing the impacts of these changes in our frequency of flood events and droughts and shifts in the hydrograph, and that ignoring these changes in managing our river resources is unwise. The notion that climate "stationarity is dead" is well accepted in the water resources profession and it is important to include this change in any long term planning. With the longevity of FERC licenses, it is especially important that changes in climate be considered in the many studies that are being proposed to supplement this review process and in the final FERC relicensing process.

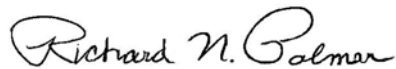

From our studies we anticipate that in the future, on average, there will be higher streamflows throughout the Connecticut River basin and this will have positive impacts on the quantity of hydropower that can be produced by the systems under study. However, climate change will increase the need to evaluate a wider range of possible operating alternatives and policies to deal with this change over time and to evaluate the impacts of the change, along with reservoir operations, on the aquatic resources in the river.

Although it would be easy to simply use the past as a guide to the future in terms of expected streamflows in the Connecticut River basin, we would strongly urge you against taking this approach. Because there is significant research on the climate impacts on streamflows in the Connecticut River basin, and because they suggest significant changes from the flow regimes of the past, ignoring these changes in the FERC process could lead to erroneous assumptions about future conditions and, in turn, inaccurate results.

We hope that as you review the comments from stakeholders and explore the proposed additional studies, that you will conclude that climate change projections should be a fundamental ingredient in all future work. Relying on the past 50 years for streamflow data in evaluating these facilities will be insufficient without an understanding of the changes in flows that are likely ahead during the next 50 years.

Thank you for considering this request.

Sincerely,

A handwritten signature in cursive script that reads "Richard N. Palmer".

RE: Northfield Mountain Pumped Storage Project No. 2485-063
Turners Falls Project No. 1889-081
Comments on the Preliminary Application Document, Scoping Document 1, and Study Requests

Dear Secretary Bose,

The Franklin Conservation District (District) was established in the 1940's under Massachusetts General Law, Chapter 21, Sections 18-25 as a quasi-state agency for the purpose of delivering conservation programs at the county level. The purposes of Conservation Districts in Massachusetts are: to focus attention on land, water and related resource problems; to develop programs to solve them; to enlist and coordinate help from all public and private sources that can contribute to accomplishing the District's goals; and to make citizens aware of the interrelationships between human activities and the natural environment.

The Conservation District has been intimately involved with efforts to address erosion on the reach of the Connecticut River from the Turners Falls dam to the Vernon dam, also known as the Turners Falls Pool, since the 1980s. In fact, it was the work of the District in conjunction with the former Franklin County Planning Board that led the Franklin County Commission to form the Connecticut River Streambank Erosion Committee (CRSEC) that has been working with the various utility companies that have owned and operated the Northfield Mountain Pumped Storage Project, with affected landowners and state and federal resource agencies, and with the FERC to address the long-term and ongoing exacerbated erosion of riverbanks in the Pool.

The District appreciates the opportunity to submit comments on the Preliminary Application Document (PAD) and Scoping Document 1, and to submit Study Requests for the projects. The comments on the PAD and Scoping Document 1 are organized by the major sections in each document. We describe some of the Study Requests that we support at the end of this letter. The specific study requests that the District is asking to be undertaken are contained in the Appendix to this letter. Finally, we note an additional issue to draw it to the attention of the FERC.

Comments on Pre-Application Document

Section 3.4.1

It is important to note the omission of the erosion articles in the licenses, Articles 19 of P-1889 and 20 of P-2485. Given the severity of bank erosion and the continuing struggle over license compliance related to these articles, they are critically important current license requirements.

Section 4.2.4

The PAD provides an incomplete and inaccurate portrayal of the conclusions of the 1979 ACOE report regarding the Turners Falls Pool. That report found this was the most hydrodynamically active stretch of the Connecticut River and that water level fluctuations caused by hydropower project operations were the largest contributor, after tractive force, to the exacerbated erosion.

The discussion of the 1991 ACOE follow up study and report omits mention of the fact that it documented a dramatic increase in the extent of eroded riverbank since the 1979 report.

The discussion of the Full River Reconnaissance Studies states that 2008 FRR reports that erosion is decreasing; it should be noted that the report and the methodology employed have been widely criticized and the conclusion vigorously disputed.

Section 4.3.1.4

This section fails to mention that the Licensee is forcing farmers to apply to the Licensee for a permit to withdraw irrigation water from the Connecticut River, saying it is a requirement of their FERC license. That is an arguable contention. This issue merits attention and resolution.

Comments on Scoping Document 1

The District offered detailed comments on the Scoping Document at the January 31, 2013 Joint Evening Scoping meeting in Turners Falls. Rather than repeat them here, the District notes and incorporates by reference the issues cited in that testimony and offers one additional comment.

Section 3.0

The District urges consideration of an alternative to the applicant's proposed action, specifically taking Northfield Mountain Pumped Storage Project off-stream, entirely or at least partially. This would be accomplished by creating and using a lower reservoir other than the Connecticut River.

Study Requests

The District supports many of the study requests of which it is aware and is making three, which are included in full in Appendix 1. In general terms they are:

- Study shoreline erosion caused by Northfield Mountain Pumped Storage (NMPS) operations
- Study the impacts of NMPS and Turners Falls dam on sedimentation in Connecticut River
- Study the feasibility of converting NMPS to a closed-loop or partially closed-loop system

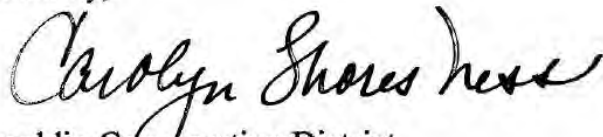

Additional Issue

Administrative support for Connecticut River Streambank Erosion Committee (CRSEC)

Given the amount of time and resources necessary for the CRSEC to keep regional, state, and federal governmental entities, non-governmental organizations, and citizens adequately informed of and involved with addressing the erosion issue, it is reasonable that the licensee, benefitting economically from its use of a valuable public resource, provide annual funding to help support the administrative functions of the CRSEC, e.g. organizing and staffing meetings, etc.

Thank you for the opportunity to comment on these documents and important issues.

Sincerely,

A handwritten signature in cursive script that reads "Carolyn Shores Hesse".

Franklin Conservation District

Vice Chair

Appendix 1

Franklin Conservation District's Study Requests

Study Request 1 - Study of Shoreline Erosion Caused by Northfield Mountain Pumped Storage (NMPS) Operations

Development of the current configuration of the Northfield Mountain Pumped Storage project included raising the dam height at Turners Falls by 5.9 feet in 1970 in preparation for NMPS operations. Operations began in 1972; since then all project operations have operated under this raised dam environment. The additional 5.9 foot in elevation changed the elevation of the Turners Falls impoundment, which extends some 20 miles upstream. The increase in river elevation also resulted in motorized boat traffic becoming more popular and makes the use of larger boats more possible. The presence of motorized recreational boats increases wake energy that can accelerate bank erosion rates.

The operation of NMPS causes alterations to the river as a direct feature of plant functionality. The alterations include: 1) daily fluctuating pond levels which at times in some places can exceed six feet (the license allows fluctuations up to 9 feet measured at an undisclosed location near and upstream of the Turners Falls dam), 2) altered flow and velocity profiles of river and 3) changes to the downstream hydrograph. Elevation data for the river in Appendix E of the PAD indicate that stage changes of 2 to 3 feet during the summer of 2012 were not uncommon.

Raising the level of the river can saturate bank soils. These same soils can quickly become dewatered when the river is lowered by the NMPS pumping cycle. Repeated saturation and dewatering of banks can lead to bank instability which in turn can lead to bank failure and eroded material entering the river. See Field (2007)¹ for an extended discussion on bank erosion and failure mechanics. Elevated levels of turbidity and suspended solids in the water column can diminish rearing and migratory habitat for fish. When too much fine grain material is deposited on channel bed substrates, particularly those substrates used for spawning, spawning success of resident and migratory fish is compromised, potentially reducing recruitment and carrying capacity.

Goals and Objectives

The goals of this study request would be to determine the environmental effects of the presence and operation of the licensed facilities on river bank stability, shoreline habitat, agricultural farmland, wetland resources, bed substrate, and water quality in the Turners Falls impoundment. We recognize that data from other studies will be made available and we think that the data from these other studies could be used to help meet the objectives of this study request.

Objectives of the study include the following:

1. Calculate the total volume of eroded material, calculate resulting nutrient loading of eroded material, and document and describe the three dimensional changes to the bank, including lateral bank recession, changes to bank slope, and the presence and subsequent

¹ Field Geology Services. (2007). *Fluvial geomorphology study of the Turners Falls Pool on the Connecticut River between Turners Falls, MA and Vernon, VT*. Prepared for Northfield Mountain Pumped Storage Project. Farmington, ME: Field Geology Services.

inundation of pre-project beaches and shoreline since the Turners Falls Dam was raised and the Northfield Mountain Pumped Storage facility came on-line.

2. Document and describe the changes to banks upstream and downstream of riverbank restoration projects, including bank recession.
3. Identify the changes that have occurred to bed substrate as a result of fine grain material being eroded from the banks and being deposited on the channel bed.

Relevant Resource Management Goals and Public Interest Considerations

Among our management goals is to ensure high quality habitat for migratory diadromous fish. Shortnose sturgeon, American shad and American eel all require suitable spawning, rearing, migratory and foraging habitat. Eroding banks and subsequent increases in turbidity and deposition of fine grained material onto bed substrates in the Turners Falls impoundment, the bypass reach and downstream of the Turners Falls project reduces the quality of habitat for these species. Elevated levels of suspended sediment are associated with a diminution in water quality which also affects the quality of habitat encountered by trust resource species.

In addition to habitat effects, soil erosion contributes to nutrient loading. In 2001, the U.S. EPA approved New York and Connecticut's Long Island Sound (LIS) dissolved oxygen TMDL. As a result, the New England Interstate Water Pollution Control Commission (NEIWPC) established the Connecticut River Workgroup and the Connecticut River Nitrogen Project. This project is a cooperative effort involving staff from NEIWPC, the states of Connecticut, Massachusetts, New Hampshire, and Vermont, and EPA's Region 1 and Long Island Sound (LIS) offices. All are working together to develop scientifically-defensible nitrogen load allocations, as well as an implementation strategy, for the Connecticut River Basin in Massachusetts, New Hampshire, and Vermont that are consistent with TMDL allocations established for LIS. Since its inception, the Connecticut River Workgroup has participated in a number of projects to better understand nitrogen loading, transport, and reductions in erosion.

Public Interest Considerations if Requester is not a Resource Agency.

The Franklin Conservation District (District) was established in the 1940's under Massachusetts General Law, Chapter 21, Sections 18-25 as a quasi-state agency for the purpose of delivering conservation programs at the county level. The purposes of Conservation Districts in Massachusetts are: to focus attention on land, water and related resource problems; to develop programs to solve them; to enlist and coordinate help from all public and private sources that can contribute to accomplishing the District's goals; and to make citizens aware of the interrelationships between human activities and the natural environment.

Existing Information and Need for Additional Information

The PAD makes reference to several studies in section 4.2.4 including the Erosion Control Plan (Simons & Associates, 1999), previous Full River Reconnaissance studies (1998, 2001 – maps but no report generated, 2004, and 2008), Field Geology Services' 2007 fluvial geomorphic investigation of the Turners Fall impoundment, and 2012 investigations by Simons & Associates. Field Geology Services' 2007 investigation provided several good recommendations for future work in section 9.3 of its report which, if implemented, could provide for: a) an improved understanding of the causes of erosion; b) more accurate monitoring of erosion; and c) more successful bank stabilization efforts. This document is a good point of reference. The Simons &

Associates' (2012) documents are qualitative and based on several unstated assumptions that may not be valid. Full River Reconnaissance efforts have been undertaken using varying methodologies, making for difficult comparisons from one report to the other.

We believe that these existing studies do have data that can be useful if certain new analyses are undertaken. These analyses of existing data would help fill in our gaps of understanding of bank erosion in the Turners Fall impoundment. We are also asking for some additional field collected data. With the existing information, it should be possible to better display what changes have occurred to streambanks over time. Current Geographic Information System (GIS) software allows for various types of data to be assembled into a map and into a database such that change over time analysis can be conducted fairly easily. The change over time analysis is a critical analysis that is needed, and was already started under Field (2007).

Photos that have been taken at or near the same location but at different times exist. For example, the last three Full River Reconnaissance efforts have included continuous videotaping of the river banks with locational information. With these data, "snapshots" of the bank at various locations could be extracted and compared over time. Field (2007) photo locations could be re-shot as well. This existing information should be presented such that it is easy to discern where the photo was taken and what changes have occurred over time. A comparison of the bank every 100 ft could be compared over the years.

Historic aerial photography for the Turners Fall impoundment should be gathered and analyzed. Examples of good photographic datasets include the Field 2007 appendices and 1929 aerials. The location of the shoreline over time should be noted such that it is easy to discern where bank retreat has been most severe and where the river has been relatively stable since the earliest aerial photograph was taken.

Very little turbidity data for the Turners Falls impoundment, the bypass reach or stretches of the Connecticut River downstream of the Turners Fall project exist. Thus far, implementation of the *Northfield Mountain Pumped Storage Project Sediment Management Plan* (revised February 15, 2012) has yielded few results, and many technological difficulties (see *2012 Sediment Management Plan – 2012 Summary of Annual Monitoring* dated November 30, 2012). Suspended sediment monitoring equipment is installed at the Route 10 Bridge upstream of the project and inside the powerhouse, theoretically taking readings representative of pumping and discharging through the turbines. An analysis of how turbidity might change relative to rapidly changing impoundment levels would be very useful information.

Nexus to Project Operations and Effects

The construction of the NMPS project was contingent upon the Turners Falls project raising the dam crest elevation by 5.9 feet. The NMPS project operations rely on the Turners Falls impoundment as the source of water to be pumped up and then discharged back into the river through turbines. The importance of this river reach to the NMPS operation is made clear by FirstLight's reference to this portion of the river as the "lower reservoir." Daily pumping and discharging changes the ponded elevation of the Connecticut River which in turn leads to bank material that repeatedly becomes saturated and then dewatered. Weakened bank material can then become eroded and the fine grain material from the banks can enter the water column and

be transported in suspension in the river and eventually settle onto bed material. The raising of the Turners Falls impoundment also made recreational boating more popular, including the introduction of large, high-horsepower powerboats that were not previously present. Because of the fluctuating water levels, boat wakes impact the shoreline to a much greater extent than would occur if levels were more constant, thus exacerbating both the effects of the wakes and the fluctuating levels. For these reasons, erosion caused or contributed by NMPS project operation can negatively affect spawning, rearing and migratory habitat for trust species and the endangered shortnose sturgeon. The requested study will help inform the Commission when contemplating mitigation measures and or operational modifications.

Proposed Methodology

1. This study should determine the net soil loss in cubic yards between 1970 and the present; a density estimate of the eroded material should also be provided. Provide an analysis of where the greatest loss has occurred, location of proximity to the tailrace, soil type, riparian land use, and vegetative cover in that area. Calculate nutrient loadings (nitrogen and phosphorus compounds) to the river system based on soil loss.
2. Obtain copies of the original survey plans for the project, and complete a new survey using the same landmarks used previously. The Field (2007) report states on page 11 that the original survey plans of the river are still retained by Ainsworth and Associates, Inc. of Greenfield MA. Use pre-operation aerial photos and current aerial photos to complete a 10-foot topographic map of the section of river between Turners Falls Dam and Vernon Dam and the 200-foot buffer regulated under the Massachusetts Rivers Protection Act. The Field (2007) report on page 11 states that Eastern Topographics, Inc. determined that sufficient information is known about the 1961 aerial photos (e.g., height of airplane) to create a 10-foot topographic map of that time period, and that 1961 aerial photos could be accurately overlaid with recent aerial photos. Field (2007) states that this analysis would enable a more reliable determination of small-scale shifts in channel position and changes in bank height that may have resulted from the erosion of a low bench that previously existed along portions of the river. Among other things, create a single map showing areas of erosion and deposition, and also overlay the Field report's hydraulic modeling analysis of the river channel.
3. With respect to the January 22, 2013 submittal from FirstLight to FERC regarding its long term monitoring transects in the Turners Fall impoundment, we ask that any data errors (as discussed in Field, 2007) and problems that have occurred over the years at each site be mentioned. We also ask that an analysis for each cross section extending to the top of the bank and including a portion of the floodplain be provided.
4. Take the information presented in Figure 4.2.3-1 "Soils in the vicinity of Turners Falls and Northfield Mountain projects" in the PAD and convert from 63 categories to just a few that are defined in a key that will allow readers to understand which soils are easily erodible, which aren't, and where there is bedrock along the banks.
5. Complete detailed surficial mapping (topographic map or LIDAR) to identify the various geomorphic surfaces, height of benches/terraces above the river level, and types of sediments underlying the surfaces. This will allow one to determine how erosion varies with geomorphic conditions. One could then normalize the amount of erosion to a specific type of bank material/geomorphic surface/terrace.

6. Another information request covers the range of daily water level fluctuations. In this study request, we ask for an analysis on the degree to which boat wakes increase that fluctuation range. The task would be to observe boat wakes under a range of boat sizes and flow rates on the river. We recommend implementation of the 2007 Field report recommendation that states, "A more thorough study of boat waves is merited to better document how many boats use the Turners Falls Pool, how fast they travel, the type and size of waves they produce, and their impact on shoreline erosion."

A component of this study request is not necessarily for new data, but for existing data to be presented in a more clear, coherent and comprehensive manner. All existing photographs of banks that have been collected either by FirstLight, on behalf of FirstLight or on behalf of the FRCOG Streambank Erosion Committee should be georeferenced in such a way that it is easy to discern where the photograph was taken and the date should be easily discernible as well. These photos should be presented in a manner that makes it easy to visually see how a particular section of bank has changed over time. Providing geographic context for photographic data of river banks and making these photos comparable over time should be standard practice. The 2007 Field report contains the following recommendation on page 47: "An attempt should be made to overlay the 1961 aerial photographs with a current flight and to create a topographic map from the 1961 flight. The feasibility of this effort has been confirmed by Eastern Topographics, Inc. This effort will identify the previous extent of the low bench and identify areas of the most significant bank recession the past 45 years." Given that this statement was written in 2007, we request that that the analysis is extended to current conditions.

Given the complexity of this study request and the expertise necessary to implement it, we request that we and the mandatory conditioning agencies be involved with the selection of the hired consultant.

Level of Effort and Cost
